1 Introduction 12
1.1 Device Overview 13
1.2 Functional Block Diagram 14
1.3 Module Allocation and Instances within Device Domains 15
1.4 Device MAIN Domain 15
1.4.1 Arm Cortex-A53 Subsystem (A53SS) 16
1.4.2 Programmable Real-Time Unit Subsystem (PRUSS) 17
1.4.3 DDR 16-bit Subsystem (DDR16) 17
1.4.4 Region-based Address Translation Module (RAT) 18
1.4.5 Data Movement Subsystem (DMSS) 18
1.4.6 Mailbox (MAILBOX) 19
1.4.7 Spinlock (SPINLOCK) 19
1.4.8 General Purpose Input/Output Interface (GPIO) 19
1.4.9 Inter-Integrated Circuit Interface (I2C) 19
1.4.10 Serial Peripheral Interface (SPI) 19
1.4.11 Universal Asynchronous Receiver/Transmitter (UART) 20
1.4.12 3-port Gigabit Ethernet Switch (CPSW3G) 20
1.4.13 Universal Serial Bus (USB) Subsystem 2.0 20
1.4.14 General Purpose Memory Controller (GPMC) 21
1.4.15 Error Location Module (ELM) 21
1.4.16 Flash Subsystem (FSS) with Octal Serial Peripheral Interface (OSPI) 21
1.4.17 Multi-Media Card/Secure Digital Interface (MMCSD) 22
1.4.18 Enhanced Capture Module (ECAP) 22
1.4.19 Enhanced Pulse-Width Modulation Module (EPWM) 22
1.4.20 Enhanced Quadrature Encoder Pulse Module (EQEP) 22
1.4.21 Controller Area Network (MCAN) 23
1.4.22 Timers 23
1.4.23 Internal Diagnostics Modules 23
1.5 Device MCU Domain 24
1.5.1 MCU Arm Cortex M4F Subsystem (MCU_M4FSS) 25
1.5.2 MCU General Purpose Input/Output Interface (MCU_GPIO) 26
1.5.3 MCU Inter-Integrated Circuit Interface (MCU_I2C) 26
1.5.4 MCU Multi-channel Serial Peripheral Interface (MCU_SPI) 26
1.5.5 MCU Universal Asynchronous Receiver/Transmitter (MCU_UART) 26
1.5.6 MCU Timers 27
1.5.7 MCU Internal Diagnostics Modules 27
1.6 Device WKUP Domain 28
1.6.1 Arm Cortex-R5F Processor (R5FSS) 28
1.7 Device Identification 30
2 Memory Map 31

3.1.3 Timeout Gasket 73
3.1.4 Route ID Allocation 75
3.1.5 Quality of Service (QoS) 76
3.1.6 Initiator-Side Security Controls and Firewalls 81
3.1.7 Interconnect Error Reporting Feature 92
3.1.8 Connectivity Table 92
3.1.9 QoS Programming Guide 95
3.1.10 Performance Considerations 96
4 Module Integration 97
4.1 Memory Controllers 98
4.1.1 DDR16 Subsystem (DDR16SS) 99
4.2 Processors and Accelerators 100
4.2.1 Arm Cortex A53 Subsystem (A53SS) 100
4.2.2 Arm Cortex R5F Subsystem (WKUP_R5FSS) 104
4.2.3 Arm Cortex M4F Subsystem (MCU_M4FSS) 106
4.2.4 Programmable Real-Time Unit Subsystem (PRUSS) 107
4.3 Interprocessor Communication 110
4.3.1 Mailbox 111
4.3.2 Spinlock 114
4.4 Device Configuration 115
4.4.1 Control Module (CTRL_MMR) 115
4.4.2 Pad Configuration Module (PADCFG_CTRL) 116
4.5 Data Movement Architecture 119
4.5.1 Data Movement Subsystem (DMSS) 120
4.5.2 Peripheral DMA (PDMA) 121
4.6 Audio 122
4.6.1 Multichannel Audio Serial Port (MCASP) 122
4.7 General Connectivity 126
4.7.1 General Purpose Input/Output (GPIO) 126
4.7.2 Inter-Integrated Circiuit (I2C) 132
4.7.3 Multichannel Serial Peripheral Interface (MCSPI) 137
4.7.4 Universal Asynchronous Receiver/Transmitter (UART) 140
4.8 High-speed Serial Interfaces 146
4.8.1 Gigabit Ethernet Switch (CPSW) 146
4.8.2 Universal Serial Bus Subsystem (USB) 149
4.9 Memory Interfaces 151
4.9.1 Flash Subsystem (FSS) 151
4.9.2 Octal Serial Peripheral Interface (OSPI) 152
4.9.3 General-Purpose Memory Controller (GPMC) 154
4.9.4 Error Location Module (ELM) 155
4.9.5 Multimedia Card Secure Digital (MMCSD) 156
4.10 Industrial and Control Interfaces 158
4.10.1 Modular Controller Area Network (MCAN) 158
4.10.2 Enhanced Capture (ECAP) 162
4.10.3 Enhanced Pulse Width Modulation (EPWM) 164
4.10.4 Enhanced Quadrature Encoder Pulse (EQEP) 167
4.11 Camera Subsystem 169
4.11.1 Camera Serial Interface Receiver (CSI_RX_IF) 169
4.11.2 MIPI D-PHY Receiver (DPHY_RX) 171
4.12 Timer Modules 172

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

Glossary

TI Glossary — This glossary lists and explains terms, acronyms, and definitions.

Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for the device, visit the Texas Instruments website at www.ti.com.

Below are some direct links to additional documentation:

Chapter 1

Introduction

This chapter introduces the features, subsystems, and architecture of the AM62x Sitara Processor Platform high-performance System-on-Chip (SoC).

Note

This document describes the Superset architecture, processors and peripherals of the AM62x Family of SoCs, which are part of the AM62x Multicore SoC architecture platform. Not all features are available on each family of devices. The superset AM623 and AM625 (each of which will have a single, dual and quad core option) devices are available for preproduction software development. Software should constrain the features used to match the intended production device. For more information on the specific features, processors and peripherals available on a particular device, refer to the Device Comparison table in the corresponding device-specific Data sheet.

The AM62x Sitara Processor Platforms are hereinafter commonly referred to as AM62x *platform*, *device*, or *SoC*.

1.4 Device MAIN Domain

This section describes the modules integrated in the device MAIN domain.

Copyright © 2024 Texas Instruments Incorporated

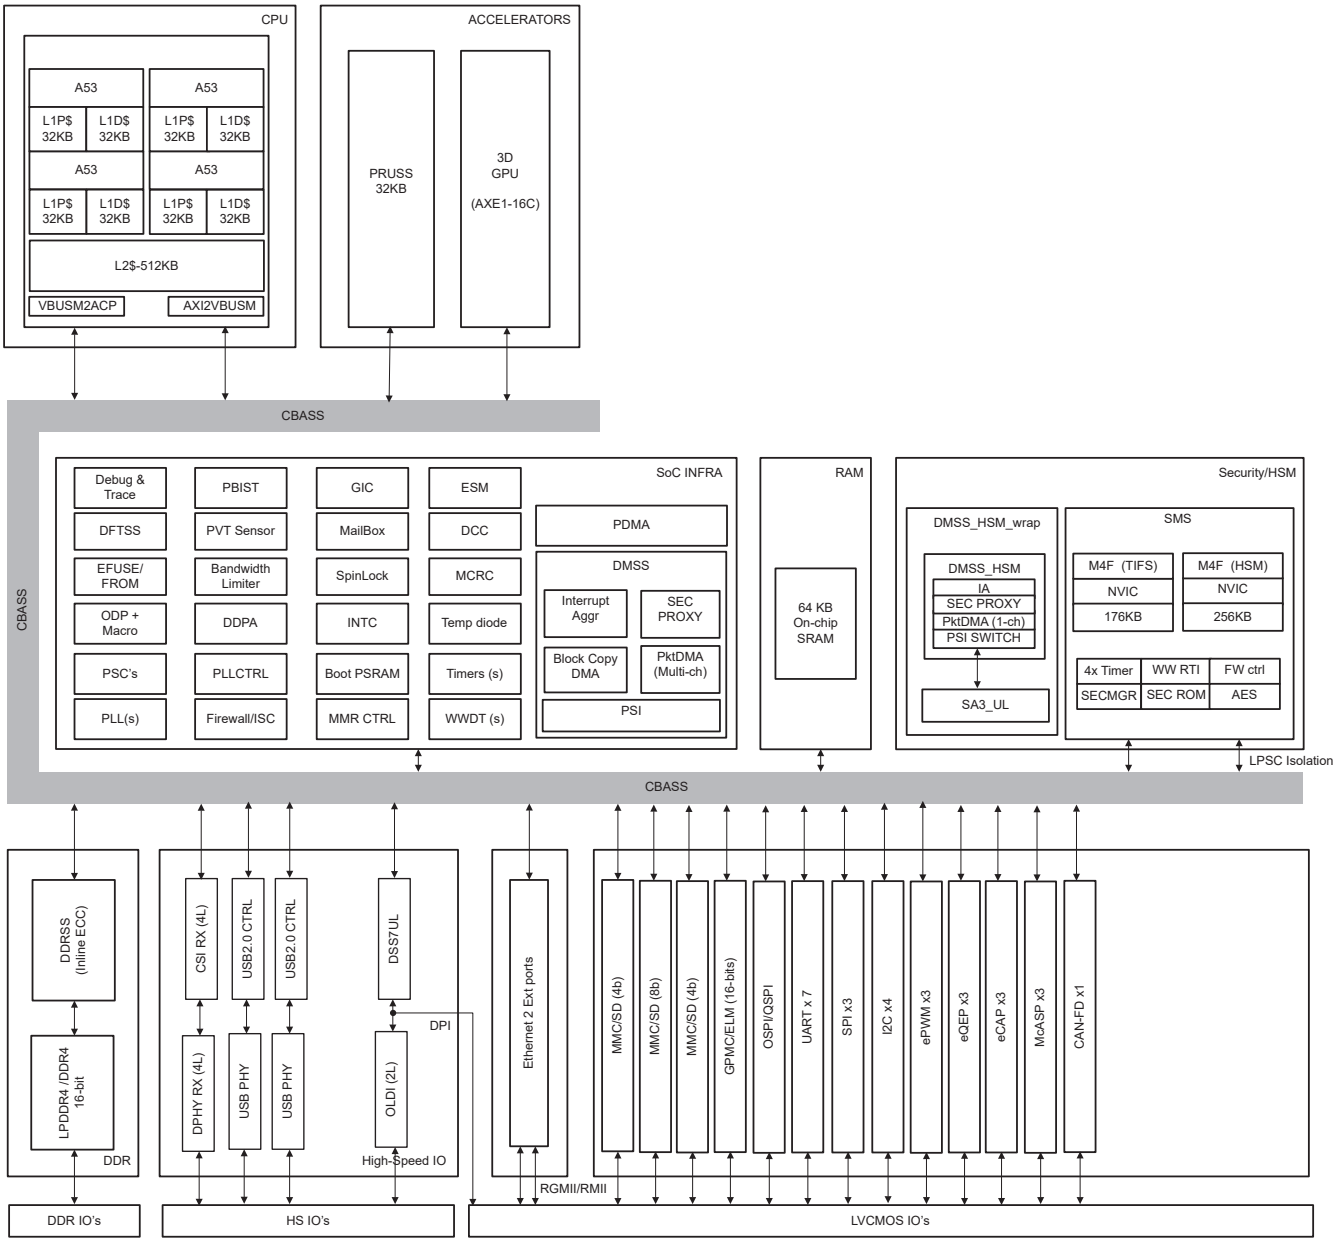

Figure 1-2. AM62x MAIN Domain Functional Block Diagram

1.4.1 Arm Cortex-A53 Subsystem (A53SS)

The integrated 64-bit Arm Cortex-A53 subsystem (A53SS) supports the following main features:

- Up to a quad-core Arm Cortex-A53 MPCore processor with L1 memory system and a single shared L2 cache.
- Full Arm®v8-A architecture compliancy
- Advanced Single Instruction Multiple Data (SIMD) and floating point extension (Arm® Neon™)
- Floating-Point Unit (FPU) VFPv4
- Armv8 Cryptography Extensions
- Arm General Interrupt Controller (GICv3) architecture
- In-order pipeline with symmetric dual-issue of most instructions
- 32KB program and 32KB data Level 1 (L1) Cache
- 512KB shared Level 2 (L2) Cache

Copyright © 2024 Texas Instruments Incorporated

- Support for up to four timers within each Cortex-A53 core
- Arm® CoreSight™ Debug and Trace Architecture
- ECC protection for L1 data cache and L2 Cache
- Parity protection for L1 Instruction Cache
- 128-bit wide, synchronous or asynchronous VBUSM initiator interface
- Dedicated RTI windowed watchdog timer per core
- Support for Big-Endian (BE) and Little-Endian (LE) at core level
- Interface with Arm GIC-500 Interrupt Controller (SoC level, not part of A53SS)
- Advanced power management for low power optimization

1.4.2 Programmable Real-Time Unit Subsystem (PRUSS)

Integrated in MAIN domain: Two instances of the Programmable Real-Time Unit Subsystem used primarily for driving GPIO for cycle accurate protocols such as additional UARTS, I2C and external ADC.

MAIN domain encompasses two identical PRUSS subsystems, each supporting the following main features, among others:

- Two Programmable Real-time Unit Subsystems (PRUSS):
  - PRU:
    - Asynchronous capture (Serial Capture Unit (SCU)] with EnDat 2.2 protocol and Sigma-Delta demodulation support
    - 20 Enhanced General Purpose Inputs (EGPI) and 20 Enhanced General Purpose Outputs (EGPO)
    - 12 KB program memory per PRU (PRU0_IRAM and PRU1_IRAM) with ECC
    - CRC16/CRC32 HW accelerator
    - RX XFR2VBUS
- Scratchpad Memory (SPAD) with 2 banks of 30 x 32-bit registers
  - 3 banks for the PRU0 and PRU1 cores
- 32KB shared general purpose RAM with ECC, shared between PRU0 and PRU1
- Two 8KB (shared) Data Memories with ECC (one per slice)
- 36-bit VBUSM Controller Port
  - Optional address translation for all transactions to External Host
- 16 Software Events generated by 2 PRUs
- One Enhanced Capture (ECAP) module
- One interrupt controller (INTC)
  - Up to 32 internal events, generated by modules, internal to the PRUSS
  - Up to 32 external events, generated by the system
  - Supports up to 10 interrupt channels
  - Generation of 18 Host interrupts
    - 2 Host interrupts tp PRU0, PRU1
    - 8 Host interrupts, exported from the PRUSS for signaling the Arm interrupt controllers (pulse and level provided)
  - Each system event can be enabled and disabled
  - Each host event can be enabled and disabled
  - Hardware prioritization of events
- One 32-bit VBUSP target port for memory mapped register and internal memories access
- Flexible power management support
- Integrated 32-bit interconnect

1.4.3 DDR 16-bit Subsystem (DDR16)

Integrated in MAIN domain: One instance of DDR 16-bit Subsystem (DDR16) (also referred to as DDRSS) is used as an interface to external SDRAM devices which can be utilized for storing program or data. The DDRSS provides the following main features:

- Support of LPDDR4 memory type (up to 1600Mbps)
- Support of DDR4 memory type (up to 1600Mbps)

Copyright © 2024 Texas Instruments Incorporated

- 16-bit memory bus interface with in-line ECC
- Up to 8 GB memory address range
- Support of dual rank configuration
- Support of automatic idle power saving mode when no or low activity is detected
- Class of Service (CoS) - three latency classes supported
- Dynamic change of refresh reach via SW for extended temperatures
- Prioritized refresh scheduling
- Statistical counters for performance management

1.4.4 Region-based Address Translation Module (RAT)

Integrated in MAIN domain: One instance of the Region-based Address Translation (RAT) module to perform a region based address translation of a 32-bit input address into a 36-bit output address. The RAT module provides the following main features:

- 4 regions with dedicated registers for attributes configuration:
  - Region base address
  - Region size
  - Translated base address
- Address translation for only enabled regions
- Region boundary crossing transactions error generation

1.4.5 Data Movement Subsystem (DMSS)

Integrated in the MAIN domain:One Data Movement subsystem named DMSS can be used for efficient transfer of data support between software, firmware and hardware in all combinations. It consists of the following main modules:

- Packet DMA Controller
- Block Copy DMA Controller
- Ring Accelerator provides hardware acceleration to enable straightforward passing of work between a producer and a consumer and has the following main features:
  - Supports up to 20 independent memory-mapped ring structures
  - Supports various modes for each ring based on usage and compatibility
  - Provides single-word deep shared incoming Transfer Response FIFO
  - Provides bit-wide source VBUSM read/write target interface for accesses from DMA controller entities
- Secure proxy module is a modified version of the proxy module and in addition has the following main features:
  - Provides proxy function to store large data bursts that a host can only access in smaller amounts
  - Supports a configurable number of threads, where each has their own independent proxy function
  - Keeps the large data burst coherent until the complete data has been accessed
  - Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
  - Supports a configurable target resource. The target has a configurable number of channels, size of each channel and base address
  - Supports a programmable fixed queue for each proxy thread
  - Supports multiple producers all writing to the same queue
  - Supports programmable thresholds for when to generate events
  - Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
  - Optionally supports dynamic clock gating
- Interrupt Aggregator modules provide a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Main features are as follows:
  - 64-bit VBUSP target using 64-bit registers
  - Provide a set of TI Interrupt Architecture compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.

Copyright © 2024 Texas Instruments Incorporated

- Provides an optional set of Unmapped event (UNMAP) which can take an 'unmapped' event from the ingress ETL and generate a Global event on the egress Event Transport Lane (ETL) interface.
- Provides an optional set of Global Event Input (GEVI) counters which can count events delivered via an ingress Event Transport Lane (ETL)
- Provides an optional set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
- Provides an optional set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces

1.4.6 Mailbox (MAILBOX)

Integrated in MAIN domain: One Mailbox (MAILBOX) module to facilitate the communication between the various on-chip processor cores of the device by providing a queued mailbox-interrupt mechanism with the following main features:

- 1x clusters
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

1.4.7 Spinlock (SPINLOCK)

One Spinlock module with (256 hardware semaphores) for synchronizing the processes running on multiple cores in the device.

1.4.8 General Purpose Input/Output Interface (GPIO)

Integrated in MAIN domain: Two General Purpose Input/Output (GPIO) modules that provide dedicated general-purpose pins that can be configured as either inputs or outputs. The GPIO modules main features include:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

1.4.9 Inter-Integrated Circuit Interface (I2C)

Integrated in MAIN domain: Four instances of the multi-controller Inter-Integrated Circuit (I2C) interface module, each with the following main features:

- 1x Instances with open-drain voltage buffers in compliance with the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- 8-bit-wide data access
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with fixed size of 32 bytes.
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous wake-up mechanisms
- Low power consumption

1.4.10 Serial Peripheral Interface (SPI)

Integrated in MAIN domain: Three instances of the Serial Peripheral Interface (SPI) module with the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four channels in controller mode, or single channel in receiver mode
- Support for various controller multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence

Copyright © 2024 Texas Instruments Incorporated

- Built-in FIFO available for a single channel

1.4.11 Universal Asynchronous Receiver/Transmitter (UART)

Instances of the configurable Universal Asynchronous Receiver/Transmitter (UART) interface module have the following main features:

- 16C750-compatible interface
- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Baud-rate from 300 bits/s up to 3.6864 Mbits/s with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

Note

Only one UART instance has support for support full modem control functions. All other UART instances will support only the TX, RX, RTS, and CTS signals.

1.4.12 3-port Gigabit Ethernet Switch (CPSW3G)

Integrated in MAIN domain: One instance of the 3-port Gigabit Ethernet Switch (CPSW3G) subsystem provides Ethernet packet communication for the device. The CPSW3G subsystem provides the following main features:

- Two external Ethernet ports with selectable RGMII and RMII interfaces and one internal Communications Port Programming Interface (CPPI) port.
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Support of eight priority level Quality Of Service (QOS) - 802.1p
- Support for Audio/Video Bridging (P802.1Qav/D6.0 and 802.1Qaz)
- Ethernet port reset isolation
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
- Differentiated Services Code Point (DSCP) Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Priority Based Flow Control (801.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)
- Store and Forward Switching
- Non-Blocking switch fabric
- Support of Time Sensitive Network - IEEE P902.3br/D2.0 Interspersing Express Traffic and IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE) with 512 ALE table entries
- EtherStats and 802.3 Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Maximum frame size of 2020 bytes
- Management Data Input/Output (MDIO) module for PHY Management
- Host port CPPI Streaming Packet Interface
- Emulation support

1.4.13 Universal Serial Bus (USB) Subsystem 2.0

Instantiated in MAIN domain: Two instances of the Universal Serial Bus (USB) subsystem with integrated USB2.0 PHY module has the following main features:

- Dual-Role Device (DRD) capability
- Support of Peripheral (aka Device) mode at High Speed (HS at 480 Mbps) and Full Speed (FS at 12 Mbps)
- Support of Host mode at High Speed (HS at 480 Mbps), Full Speed (FS at 12 Mbps), and Low Speed (LS at 1.5 Mbps)

Copyright © 2024 Texas Instruments Incorporated

- Support of Host Negotiation Protocol (HNP)
- Support of USB3 low power protocol states (U1, U2, and U3)
- USB instance contains a single xHCI compliant with xHCI 1.0 specification with internal DMA controller
- ECC on internal RAMs
- Embedded USB 2.0 PHY

1.4.14 General Purpose Memory Controller (GPMC)

One instance of the General-Purpose Memory Controller (GPMC) module. The GPMC is dedicated to interfacing with external memory devices and has the following main features:

- Support of 8- or 16-bit-wide data path to external memory devices
- Supports up to 4 independent chip-select regions of programmable size and programmable base addresses on 16MB, 32MB, 64MB, or 128MB boundary in a total address space of 1GB
- Support of the following wide range of external memories/devices:
  - Asynchronous or synchronous 8-bit wide memory or device (non-burst device)
  - Asynchronous or synchronous 16-bit wide memory or device
  - 16-bit non-multiplexed NOR flash device
  - 16-bit address and data multiplexed NOR flash device
  - 8-bit and 16-bit NAND flash device
  - 16-bit pseudo-SRAM (pSRAM) device
- Supports various interface protocols when communicating with external memory or external devices:
  - Asynchronous read/write access
  - Asynchronous read page access (4, 8, and 16 Word16)
  - Synchronous read/write access
  - Synchronous read burst access without wrap capability (4, 8, and 16 Word16)
  - Synchronous read burst access with wrap capability (4, 8, and 16 Word16)
- Supports up to 16-bit on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)

1.4.15 Error Location Module (ELM)

One instance of the Error Location Module (ELM). The ELM module works in conjunction with the GPMC and has the following main features:

- ECC calculations (up to 16-bit) for NAND support and ability to work in both page-based and continuous modes
  - 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
  - Eight simultaneous processing contexts
  - Page-based and continuous modes
  - Interrupt generation on error-location process completion

1.4.16 Flash Subsystem (FSS) with Octal Serial Peripheral Interface (OSPI)

Integrated in MAIN domain: One instance of the Flash Subsystem (FSS) module provides access to external flash devices via Octal Serial Peripheral Interface (OSPI) along with encryption/decryption and in-line ECC protection. FSS supports the following main features:

- Provides one OSPI flash interfaces
- OSPI interface supports:
  - Execute in place (XIP) operation
  - 32-byte Block Copy (BC) operation
  - ECC
- OSPI supports up to 4 devices
- OSPI supports single, dual, quad, or octal SPI devices
- The OSPI interface has independent power management for low power operations

Copyright © 2024 Texas Instruments Incorporated

1.4.17 Multi-Media Card/Secure Digital Interface (MMCSD)

Integrated in MAIN domain: Three Multi-Media Card/Secure Digital (MMCSD) controller modules with the following main features:

- One controller with 8-bit wide data bus
- Two controllers with 4-bit wide data bus
- Support of eMMC5.1 Host Specification (JESD84-B51)
- Support of SD Host Controller Standard Specification - SDIO 3.00
- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3
- eMMC Electrical Standard 5.1 (JESD84-B51)
- Multi-Media card features:
  - Backward compatible with earlier eMMC standards
  - Legacy MMC SDR: 3.3/1.8 V, 8/4/1-bit bus width, 0-25 MHz, 25/12.5/3.125 MB/s
  - High Speed SDR: 3.3/1.8 V, 8/4/1-bit bus width, 0-50 MHz, 50/25/6.25 MB/s
  - High Speed DDR: 3.3/1.8 V, 8/4-bit bus width, 0-50 MHz, 100/50 MB/s
  - HS200 SDR: 1.8 V, 0-200 MHz, 8/4-bit bus width, 200/100 MB/s
- SD card support: SDIO, SDR12, SDR25, SDR50, SDR104, DDR50
- System bus interface: CBA 4.0 VBUSM controller port with 64-bit data width and 64-bit address, little endian only
- Configuration bus interface: CBA 4.0 VBUSM with 32-bit data width, 32-bit aligned accesses only, linear incrementing addressing mode, little endian only

1.4.18 Enhanced Capture Module (ECAP)

Integrated in MAIN domain: Three Enhanced Capture (ECAP) modules provide accurate timing for different events. When not being used for event capture, its resources can be used to generate a single channel of asymmetrical PWM waveforms (configurable as either one capture input, or as one auxiliary PWM output). Each ECAP module supports the following main features:

- 32-bit time base counter
- 4 x 32 bits event time-stamp capture registers
- 4 stage sequencer (Mod4 counter), synchronized to external events
- Independent edge polarity selection for up to four sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- Interrupt capabilities on any of the four capture events
- Support of different capture modes (single shot capture, continuous mode capture, absolute timestamp capture or delta mode time-stamp capture)

1.4.19 Enhanced Pulse-Width Modulation Module (EPWM)

Integrated in MAIN domain: Three Enhanced Pulse-Width Modulation (EPWM) modules, each with the following main features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two independent PWM outputs that can be used in different configurations (with single-edge operation, with dual-edge symmetric operation or one independent PWM output with dual-edge asymmetric operation)
- Asynchronous override control of PWM signals during fault conditions
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both latched and un-latched fault conditions
- Events enabling to trigger both CPU interrupts and start of ADC conversions

1.4.20 Enhanced Quadrature Encoder Pulse Module (EQEP)

Integrated in MAIN domain: Three 32-bit Enhanced Quadrature Encoder Pulse (EQEP) modules for position, speed, and frequency measurements support, each with the following main features:

- Input synchronization
- Three stage/six stage digital noise filter

Copyright © 2024 Texas Instruments Incorporated

- Quadrature decoder unit
- Position counter and control unit for position measurement
- Quadrature edge capture unit for low speed measurement
- Unit time base for speed/frequency measurement
- Watchdog timer for detecting stalls

1.4.21 Controller Area Network (MCAN)

Integrated in the domain: One Controller Area Network interfaces (MCAN) supporting both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications and having the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

1.4.22 Timers

Three different types of timer modules are instantiated in the MAIN domain:

- One instance of Global Time Counter (GTC) module that can be used for time synchronization and debug trace time stamping with the following main features:
  - 64-bit up counter
  - No rollover during the lifetime of the device
  - Compatible with Armv8 system counter requirements
  - Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
  - Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols
- Five instances Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Fast enabling/disabling of events
- Eight instances of the dual mode Timer (TIMER) module with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source (2^n, where n = [0-8])
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
  - On-the-fly read/write register (while counting) for systems operation and benchmarking code

1.4.23 Internal Diagnostics Modules

Instantiated in MAIN domain are different internal diagnostics modules which provide monitoring and diagnostic functions required to achieve certain safety compliance levels:

Copyright © 2024 Texas Instruments Incorporated

- Seven Dual Clock Comparator (DCC) modules, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement
- One instance of Error Signaling Module (ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:
  - Up to 1024 level or pulse error event inputs
  - Selectable low and high priority interrupt error pin prioritization of each error event
  - Error signal routed out of device through MCU_ESM error signal
  - Configurable time base for error signal
  - Error forcing capability
  - Internal redundant flops on safety critical fields
- Multiple ECC aggregator modules supporting ECC mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED). Applied to different memories in many of the subsystems, each of the ECC aggregators has the following main features:
  - Reduces memory software errors via single error correction (SEC) and double error detection (DED)
  - Provides a mechanism to control and monitor the ECC RAMs in a module or subsystem
  - Supports software readable status of ECC errors (single and double-bit) and associated info such as RAM address and data bit or bits that are in error
  - Aggregates level pending status from the ECC RAMs in two interrupts to the device CPU – interrupt for correctable error (SEC) and interrupt for uncorrectable error (DED)
  - Supports up to 256 ECC endpoints (either ECC RAM or interconnect ECC component)
  - Single bit error detection via parity checking results in a non-correctable error interrupt

1.5 Device MCU Domain

This section describes the modules integrated in the device MCU domain.

Note

In TI documentaiton, the MCU Domain may be referred to as "M4FSS Island", "MCU Island", "MCU Channel", or "MCU Subsystem".

The Microcontroller Unit Domain (MCU Domain) is a “chip-in-a-chip” concept and it operates using separate clock sources and resets. This allows the MCU Domain to function continuously regardless of the state of the rest of the device, including periods in which the rest of the device is held in reset or powered down. The MCU island integrates communication peripherals such as SPI, I2C, and UART which are expected to be used for safety critical communication, so if the main SoC goes down, the MCU island can communicate this information to the rest of the system. Isolation of the MCU Arm Cortex-M4F Microcontroller Subsystem helps to provide Freedom From Interference (FFI).

Copyright © 2024 Texas Instruments Incorporated

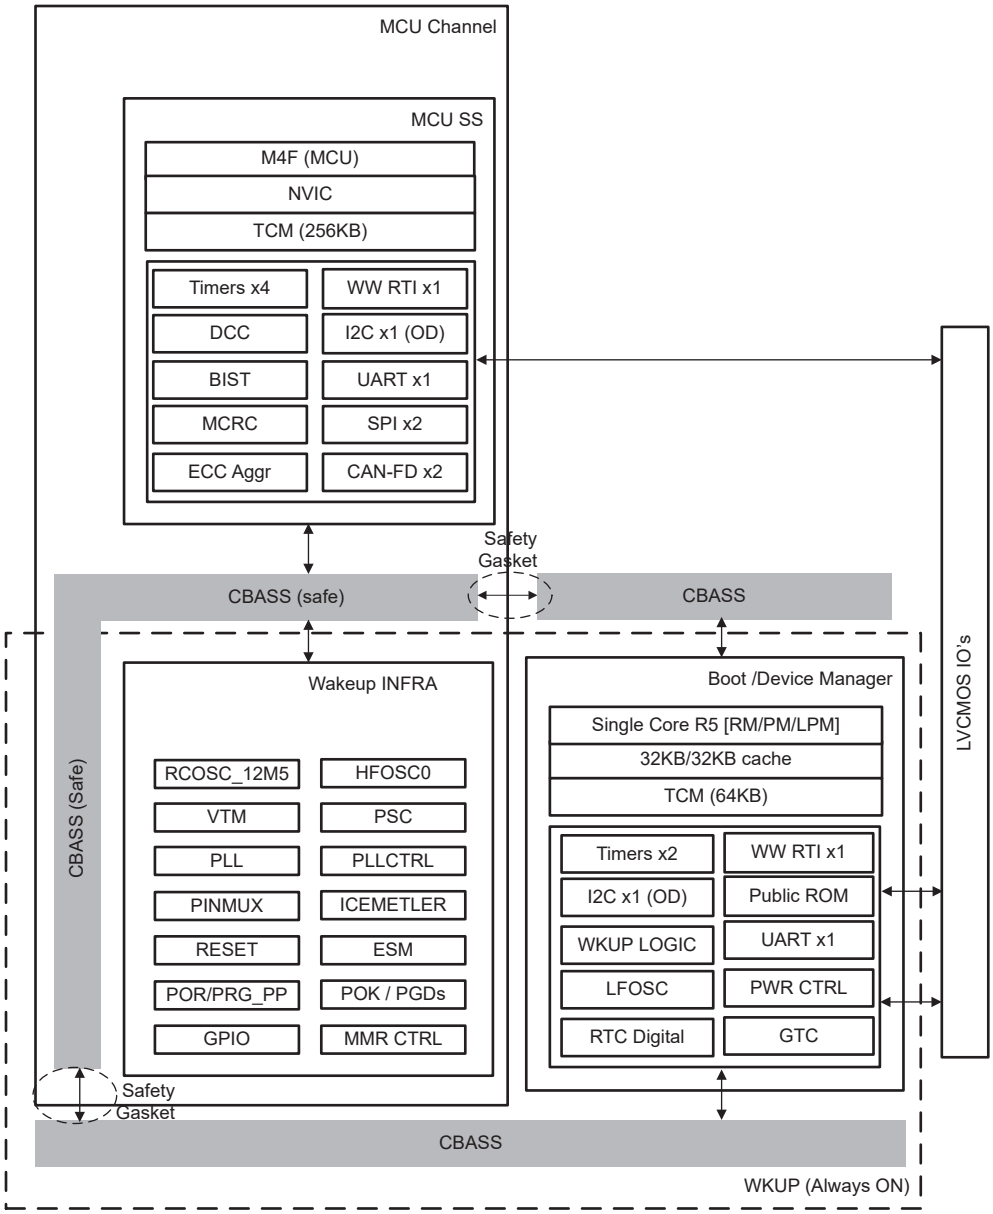

Figure 1-3. AM62x MCU Domain Functional Block Diagram

1.5.1 MCU Arm Cortex M4F Subsystem (MCU_M4FSS)

Integrated in the MCU domain: One Arm Cortex-M4F Subsystem module. This processor core can be configured as an isolated safety MCU or general purpose MCU.

- Cortex M4F With MPU
- ARMv7-M architecture
- Support for Nested Vectored Interrupt Controller (NVIC) with 64 inputs
- Ability to executed code from internal or external memories
- 192 KB of SRAM (I-Code)
- 64 KB of SRAM (D-Code)
- Debug Support Including:
  - DAP based Debug to the CPU Core
  - Full Debug Features of CPU Core are enabled
  - Standard ITM trace

Copyright © 2024 Texas Instruments Incorporated

  - CTM Cross Trigger
  - ETM Trace Support
- Fault Detection and Correction:
  - SECDED ECC protection on I-CODE
  - SECDED ECC protection on D-CODE
  - Fault Error Interrupt Output

1.5.2 MCU General Purpose Input/Output Interface (MCU_GPIO)

Integrated in MCU domain: One General Purpose Input/Output (MCU_GPIO) module provides dedicated general-purpose pins that can be configured as either inputs or outputs. the MCU_GPIO module includes these main features:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

1.5.3 MCU Inter-Integrated Circuit Interface (MCU_I2C)

Integrated in MCU domain:One multi-controller Inter-Integrated Circuit (MCU_I2C) interface with the following main features:

- Compliancy to the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with programmable size of 8 to 64 bytes for buffered read or write
- 8-bit-wide data access
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous Wakeup mechanisms
- Low power consumption

1.5.4 MCU Multi-channel Serial Peripheral Interface (MCU_SPI)

Integrated in MCU domain: Two Multi-channel Serial Peripheral Interface (MCU_SPI) modules where each have the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of MCSPI word lengths, ranging from 4 to 32 bits
- Up to four controller channels, or single channel in receiver mode
- Support of different controller multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

1.5.5 MCU Universal Asynchronous Receiver/Transmitter (MCU_UART)

Integrated in MCU domain: One configurable Universal Asynchronous Receiver/Transmitter (MCU_UART) interface with the following main features:

- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- 16C750 compatible interface
- Baud rates up to 3.6 Mbps with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

Copyright © 2024 Texas Instruments Incorporated

1.5.6 MCU Timers

Two different types of timer modules are instantiated in the MCU domain:

- One instance Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Windowed Watchdog Timer (WWDT) feature
  - Some RTI modules are pre-dedicated to specific processor cores
- Four instances of Timer module with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source (2n, where n = [0-8])
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
  - On-the-fly read/write register (while counting) for systems operation and benchmarking code
  - Each odd numbered timer instance may be optionally cascaded with the previous even numbered timer instance to form up to a 64-bit timer

1.5.7 MCU Internal Diagnostics Modules

Instantiated in MCU domain are different internal diagnostics modules which provide monitoring and diagnostic functions required to achieve certain safety compliance levels:

- One instance of the Dual Clock Comparator (MCU_DCC) module, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement
- One instance of Error Signaling Module (MCU_ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:
  - Up to 1024 level or pulse error event inputs
  - Selectable low and high priority interrupt error pin prioritization of each error event
  - Single Error Pin output to signal severe device failure to outside world
  - Configurable time base for error signal
  - Triple Redundant Pulse Inputs
  - Two Priority Levels
  - Error Forcing capability
  - Internal redundant flops on safety critical fields
- Multiple ECC aggregator modules supporting ECC mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED). Applied to different memories in many of the subsystems, each of the ECC aggregators has the following main features:
  - Reduces memory software errors via single error correction (SEC) and double error detection (DED)
  - Provides a mechanism to control and monitor the ECC RAMs in a module or subsystem
  - Supports software readable status of ECC errors (single and double-bit) and associated info such as RAM address and data bit or bits that are in error

Copyright © 2024 Texas Instruments Incorporated

  - Aggregates level pending status from the ECC RAMs in two interrupts to the device CPU – interrupt for correctable error (SEC) and interrupt for uncorrectable error (DED)
  - Supports up to 256 ECC endpoints (either ECC RAM or interconnect ECC component)
  - Single bit error detection via parity checking results in a non-correctable error interrupt
- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system. The MCRC module has the following main feature:
  - Four Channels of CRC Compression based Signature Generation
  - 8, 16, 32, or 64-bit Data Size
  - Maximum Length PSA based on 64-bit Polynomial
  - Programmable 20 bit pattern counter per channel
  - Three Operating Modes: Auto, Semi-CPU, Full CPU
  - MCRC or CPU can perform signature verification for each Channel
  - Timeout Interrupt if CRC is not performed within the time limit

1.6 Device WKUP Domain

This section describes the modules integrated in the device WKUP domain.

1.6.1 Arm Cortex-R5F Processor (R5FSS)

The ARM Core Cortex-R5F processor subsystem (R5FSS) supports the following main features:

- Armv7-R architecture
- R5FSS Memory System
  - 32KB Instruction Cache
    - 4x8KB ways
    - SECDED ECC protected per 64 bits
  - 32KB Data Cache
    - 4x8KB ways
    - SECDED ECC protected per 32 bits
  - 64KB tightly-coupled memory (TCM) per CPU
    - SECDED ECC protected per 32 bits
    - TCM hard error cache Implemented in CPU
    - Readable/writable from system
    - TCMs initialized (to 0's) at reset
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Full-precision Floating Point (VFPv3)
- 16-region Memory Protection Unit (MPU)
- 8 breakpoints, 8 watch points
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface (CTI, ETM)
- Performance Monitoring Unit (PMU)
- 32-bit to 36-bit Region-based Address Translation (RAT) on memory access initiators
- Integrated Vectored Interrupt Manager (VIM) per core with 256 Interrupt Inputs each
  - Programmable interrupt priority (4-bit)
  - Programmable interrupt enable mask
  - Software-generated interrupts
  - Synchronous clock domain crossing on all core interfaces

Note

CORE0 has 64KB of TCM.

1.7 Device Identification

The device part number identification data can be read in the WKUP_CTRL_MMR_CFG0_JTAG_USER_ID register. See Table 1-1 for more information.

Table 1-1. Device Part Number Identifier

WKUP_CTRL_MMR_CFG0_JTAG_USER_ID Register Field	Value and Description	Comment
[31-13] DEVICE_ID	Base Part Number.	Refer to the Device Comparison table in the device specific datasheet for the combined DEVICE_ID and FEATURES value of a given part number
[12] SAFETY	0 = Non Functional Safety 1 = Functional Safety	
[11] SECURITY	0 = Non-Secure 1 = Secure	
[10-6] SPEED	Device Speed Grade. 1 (0x01) = A speed designator 2 (0x02) = B speed designator … 25 (0x19) = Y speed designator 26 (0x1A) = Z speed designator	Refer to the device-specific Datasheet for the supported speed grades and the definitions for a given device.
[5-3] TEMP	Temperature grade. 3 = 0°C to 95°C 4 = -40°C to 105°C 5 = -40°C to 125°C Others = Reserved	Operating junction temperature range.
[2-0] PKG	Package 1 = ALW 6 = AMC Others = Reserved	Device Package type.

The manufacturer identity, the boundary scan part number, and the silicon revision of the device can be read in the WKUP_CTRL_MMR_CFG0_JTAGID register. See Table 1-2 and Table 1-3 tables for more information.

Table 1-2. Device JTAG ID

WKUP_CTRL_MMR_CFG0_JTAGID Register Field	Value	Comment
[31-28] VARIANT	See Table 1-3	Silicon Revision (SR) identifier.
[27-12] PARTNO	See Table 1-3	Part number for boundary scan.
[11-1] MFG	0x277F	Manufacturer identity (TI).
[0] LSB	0x1	Always reads 1.

Table 1-3. Device JTAG ID Values

Silicon Type	VARIANT	PARTNO	WKUP_CTRL_MMR_CFG0_JTAGID Register Value

Chapter 2

Memory Map

AM62 SoC level memory map is constructed using 36b physical address and follows the guideline to put peripheral at 64KB aligned boundary. No virtual address is supported on the SoC level. However, A53 core can support virtual address internally. If software utilizes the address more than 36b, only the lower 36b is used for SoC level address decoding and the upper address bits will be ignored by the SoC. Not all the 36b memory regions are implemented by AM62. Any transactions hitting the unimplemented address range will be terminated and routed to null end point to avoid system hang. An interrupt will be asserted and the above transaction will be logged.

All the SoC level peripherals and processors use the common SoC memory except the 32b only processors, such as M4F core and R5 core. For those processors and peripherals which natively only supports 32b physical address, the Region based Address Translation (RAT) module is used to remap the 32b address into the common 36b SoC address map.

AM62 contains three domains: main domain, mcu domain and wkup domain. The following sections shows the detailed memory map in each domain.

2.1 Memory Maps 32
2.2 SoC Address Aliasing 46
2.3 Processor Memory Map View 46

2.2 SoC Address Aliasing

In general, a single end point has a unique address assignment in the common SoC memory map. However, there are some exceptions.

The I/D RAM for HSM M4F has two sets of the SoC level address assignments shown in Table 2-2. The purpose of this SoC level address aliasing is to provide a single continuous memory view for TIFS core, if the TIFS code is more than 276KB by utilizing the HSM's I/D RAM.

Table 2-2. AM62 SoC Level Address Aliasing

Memory End Points	Size	SoC address	Aliased address in the common 36b SoC address map
hsm_sram0_0	128K	0x43C0_0000	0x4408_0000
hsm_sram0_1	32K	0x43C2_0000	0x440A_0000
hsm_sram0_2	16K	0x43C2_8000	0x440A_8000
hsm_sram0_3	16K	0x43C2_c000	0x4406_c000
hsm_sram1	64K	0x43C3_0000	0x4407_0000

2.3 Processor Memory Map View

Since AM62 is built on 36b physical address, there are memory regions beyond 4GB address, such as DDR data space and debug configuration space. This is not a problem for the ARM V8 core such as A53, since it supports up to 44b physical address. However, for the micro control processor such as M4F and R5, the processor only natively supports 32b physical address space. In order to allow those micro controllers accessing the full 36b physical address space, a region based remapping module is dedicated for each processor.

2.3.1 A53 Memory View

All the A53 cores use the common 36b SoC memory map shown in Section 2.1 for its physical address map. Since A53 natively supports up to 44b physical address, if A53 issues any transaction with non-zero upper 8 physical address bits, those upper 8 address bits are ignored by SoC address decoding logic.

Sitara's SoC memory map is constructed to allow software utilizing bigger MMU page. The majority of the peripherals are put at 64KB aligned boundary. This is to allow A53 software to use 64KB MMU page to manage individual peripherals instead of using 4KB MMU page. There are a few exceptions.

Main domain GPIO is implemented by using two GPIO modules. However, these two GPIO modules are putting back to back together. Software needs to manage two GPIO modules using a single MMU page. Since each GPIO pin is managed by a single bit inside GPIO registers, there is no virtual machine or OS isolation implemented.

SoC also contains multiple DCC modules and they are put at 4KB boundary instead of 64KB. A53 software can still use 64KB MMU page to manage those DCC modules. If any of the DCC needs to be allocated for other processors, the region-based firewall can provide the additional isolation needed. The firewall granularity is at 4KB boundary, which allows each DDC is assigned individually.

Copyright © 2024 Texas Instruments Incorporated

Firewall, QoS, ISC configurations are not on 64KB boundary. And each individual firewall module, QoS module and ISC module are put at 1KB boundary.

2.3.2 HSM M4F Memory View

HSM M4F micro-controller core is natively 32b processor. A dedicated RAT module is added to allow M4F processor to access full 36b common SoC address map.

Table 2-3. HSM M4F Memory View

Start Address (32 bit)	End Address (32 bit)	Which end points HSM M4F access?	Additional Notes
0x0000_0000	0x0002_FFFF	**HSM SRAM –Bank0**	Other initiators use address 0x43C0_0000 and aliased address 0x4408_000

0x4430_0000	0x443F_FFFF	transaction will be gracefully terminated. M4F receives an exception.	
0x4440_0000	0x4440_FFFF	transaction will be gracefully terminated. M4F receives an exception.	
0x4441_0000	0x4441_FFFF	transaction will be gracefully terminated. M4F receives an exception.	
0x4442_0000	0x447F_FFFF	transaction will be gracefully terminated. M4F receives an exception.	
0x4480_0000	0x44FF_FFFF	**DMSS_HSM Interface**	
0x4500_0000	0x45FF_FFFF	**Firewall /ISC/QoS configuration**	
0x4600_0000	0x5FFF_FFFF	**transaction will be gracefully terminated. M4F receives an exception.**	
0x6000_0000	0xDFFF_FFFF	**Any transactions hitting this address range go through RAT address re-mapping to 36b common SoC memory map except address range 0x4370_0000 to 0x47FF_FFFF**	
0xE000_0000	0xE000_0FFF	**HSM M4F ITM**	Other initiators can't access those end points.
0xE000_1000	0xE000_1FFF	**HSM M4F DWT**	
0xE000_2000	0xE000_2FFF	**HSM M4F FBP**	
0xE000_E000	0xE000_EFFF	**HSM M4F SCS**	
0xE004_1000	0xE004_1FFF	**HSM M4F ETM**	
0xE004_2000	0xE004_2FFF	**HSM M4F CTI**	
0xE004_3000	0xE004_0003	**HSM M4F REVID**	
0xE00F_F000	0xE010_0000	**HSM M4F ROM Table**	
0xE010_0000	0xFFFF_FFFF	**Reserved**	

The address aliasing implemented on the SoC level allows HSM M4F and other initiators uses the I/D SRAM for both HSM and TIFS as a single continuous memory block.

2.3.3 MCU M4F Memory View

MCU domain has a M4F micro-controller core, which is natively 32b processor. A dedicated RAT module is added to allow M4F processor to access full 36b common SoC address map.

Copyright © 2024 Texas Instruments Incorporated

Table 2-4. MCU M4F Memory Map View

CortexM4 Start Address (32 bit)	CortexM4 End Address (32 bit)	Which end points MCU M4F will access	Additional Description
0x0000_0000	0x0002_FFFF	**MCU M4F's I-RAM**	Other initiator access MCU M4F's I-RAM using address 0x0500_0000
0x0003_0000	0x0003_FFFF	MCU M4F's D-RaM	Other initiator access MCU M4F's I-RAM using address 0x0504_0000
0x0004_0000	0x0083_FFFF	**Any transactions hitting this address range coming from MCU M4F will go through RAT for address re-mapping before reaching other end points.**	Can be mapped to any memory regions in the SoC common memory map except MCU M4F's I/D RAM.
0x0084_0000	0x441F_FFFF	**Reserved region. Any transaction coming from M4F hitting this region will be gracefully terminated**	
0x4420_0000	0x4420_0FFF	**MCU M4F core's RAT config**	Other initiators access this end point using the SoC common memory map place MCU M4F's RAT config at 0x05FF_0000

0xE010_0000	0xFFFF_FFFF	**Any transactions hitting this address range coming from MCU M4F will go through RAT for address re-mapping before reaching other end points.**	

2.3.4 WKUP R5 Memory View

AM62 has one single R5 core in the wakeup domain. R5 is a native 32b processor, which R5 core itself can only generate transactions using 32b address. A dedicated RAT module is integrated for this single core R5 to allow R5 software to remap the 32b R5 address into the common 36b SoC address.

In addition, R5 core has its own TCM, which R5 core can access with its TCM with a single R5 core cycle. Those TCM memories have two sets of address, one set address is used for R5 core for a single cycle access to those TCM. The second set of address is used by other initiators outside this R5 subsystem to access those TCM. R5

Copyright © 2024 Texas Instruments Incorporated

core shall always uses the first set of address to access its TCM. If R5 core utilizes the second set of address to those TCM, R5 core will receives an exception, since those transactions will be routed to be terminated by sending them to the null end point.

While the SoC level address for TCM is fixed, the address used by R5 to access to its own TCM can be remapped by software. By default, AM62 puts R5's ATCM at address 0x0 and the BTCM address at 0x4101_0000.

R5 also has one section of the region dedicated for peripheral access from address 0x2000_0000 to 0x2FFF_FFFF. This memory region is treated as normally memory, which can't be cached. R5 accesses this memory region through a dedicated single-issue interface, and none of the transactions accessing this memory region can be remapped by using RAT module.

R5 core accesses its own ATCM and BTCM memory directly, and there is no address remapping for those access. All the other access than ATCM, BTCM and address range 0x2000_0000 to 0x2FFF_FFFF from R5 core go through RAT module, which could be remapped into different address to access the rest of the SoC using the common 36b SoC memory map.

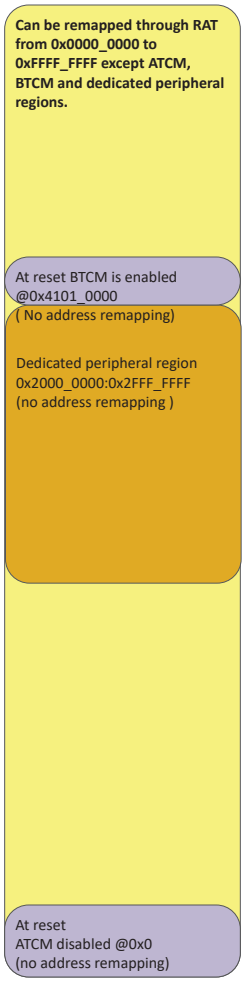

Figure 2-1. WKUP R5 32b Address Map View (Default)

The common SoC memory map assigns R5's ATCM and BTCM to address 0x7800_0000 and 0x7810_0000. R5 software can optionally reprogram the its internal ATCM and BTCM address to match the address assigned by the common SoC memory map as well. Regardless where R5 puts its own ATCM and BTCM, R5 accesses its own ATCM and BTCM directly without going through RAT.

Copyright © 2024 Texas Instruments Incorporated

ATCM is by default disabled at address 0x0. BTCM is by default enabled and the default address for BTCM is 0x4101_0000. The base address of VIM is at 0x2FFF_0000 and the base address for RAT configuration is at 0x2FFE_0000.

All the R5 transactions can go through RAT for address re-mapping function except the transactions targeted to address range 0x2000_0000 to 0x2FFF_FFFF and its own ATCM and BTCM. It is highly recommended only remap R5's address range from 0x8000_0000 to 0xFFFF_FFFF to access the target region located at the common memory map between 0x8000_0000 and 0xF_FFFF_FFFF.

2.4 Memory Map Summary

Since different type of the processors have different memory map views, this section provides a summary on how each type of processor and initiator access various target end points within the SoC.

Table 2-5. Memory Map Summary

2.5 MMU Optimization Note

The SoC memory map is constructed to enable using a larger MMU page to be 64KB and above. The system resource which can be owned by each individual software process is put at 64KB aligned memory boundary to provide the isolation among processes through MMU. Most of the simple end point peripherals are put at 64KB boundary for this purpose. The following are a few exceptions.

The debugSS_wrap contains multiple small mregions than 64KB. The main use case is to have a single SW process will own debug configuration.

GPIO modules are another exception. Each LVCMOS pin for SoC can be configured as a GPIO pin. Currently each GPIO module can provide up to 144 GPIO pins. The main domain and wkupmcu domain have separate LVCMOS IO control. In the main domain, it requires two GPIO modules to cover all the LVCMOS pins. These two GPIO modules are treated as a single entity from software point of view and these two GPIO modules are put at 4KB boundary instead of 64KB.

On the mcu domain, only one GPIO module needed to cover all the LVCMOS pins.

Copyright © 2024 Texas Instruments Incorporated

SoC also contains multiple DCC modules, and they are put at back to back on the memory map instead of spacing out at 64KB boundary. The reason is that DCC modules should be owned by a single safety processor.

Firewall and Initiator Secure Control(ISC) configurations are not on 64KB boundary. The configuration for those three items is at 1KB boundary, since the security initiator owns the configuration for them. QoS block is also put at 1KB boundary instead of 64KB, since the device manager owns the configuration of the QoS block.

Chapter 3

System Interconnect

This chapter describes the device system interconnect.

3.1 System Interconnect Overview 71

Copyright © 2024 Texas Instruments Incorporated

3.1 System Interconnect Overview

The SoC level interconnect consists of multiple types of components:

- CBASS: this is a crossbar module to provide physical connection among the initiators and targets
- VBUSP interface: a single-issue interface
- VBUSM interface: a multi-issue interface
- Channel ID: channel ID for interface indicates a logical flow. All the transactions with the same channel ID coming from the same initiator interface are consider orthogonal and independent flow.
- RouteID: a unique identification of a particular initiator interface
- OrderID: a 4 bits value associated with each transaction. All the transactions from the same initiator to the same target end point with the same orderID needs to be executed in order. OrderID is also to be used to select real-time and non-real time path for the transaction. OrderID 8-15 reserved for real-time path.
- Asel: Address Selection. Asel can be either used for select a unique memory map or be used to indicate the IO coherent transactions.
- PrivID: indicates the security access group. PrivID is assigned by the ISC block.
- ISC: stands for Initiator Security Control. It is a part of the CBASS configuration parameter. Each initiator port can optionally enable ISC feature in the CBASS configuration. It provides privID and secure side band signal overwrite value for the transactions sent by the initiator. ISC can provide the overwrite value either based on the memory address or channel ID value the transaction carries. The configuration of the ISC is done through the VBUSP configuration port from the CBASS IP.
- Region based firewall: this is firewall block based on address region.
- Channelized firewall: firewall block with finer granularity down to register level with fixed region size.
- QoS: Quality of Service block is a feature which can be enabled for each CBA initiator port connecting to the CBASS. Each initiator can choose to enable the QoS feature in the CBA configuration file. The QoS block provides some QoS related sideband signals if the initiator does not provide, such as orderID, priority, epriority and etc. If the initiator port supports channel ID, the QoS block provides priority and order ID for each channel, otherwise all the transactions from that initiator port share the same priority and order ID value.

CAUTION

Since OrderID is used for ordering purpose in CBASS, changing the order ID when the system is running can cause system deadlock. Therefore, QoS configuration shall be part of the initialization steps, if the application wants to change the QoS setting from the default value.

- Initiator timeout gasket: Initiator timeout gasket is to prevent the fault propagation from the upstream interconnect, which can't provide transaction completion notification.
- Target timeout gasket: target timeout gasket is used to prevent the fault propagation from the downstream interconnect, which enters into a fault state and no longer is able to accept any new transactions.

3.1.1 Domain Partition

SoC is partition into several domains, which are connected by CBASS modules:

- MAIN domain: there are multiple CBASS components providing the connectivity among initiators and target interfaces for the processors and peripherals in the main domain. The main application processor such as A53SS is located.
- WKUP domain: this is where the device manger R5FSS is located. This is the domain active during deepsleep mode.
- MCU domain: this is where the MCU M4FSS is located. MCU domain can be isolated from the rest of SoC during safety use case

All the modules connected to CBASS_wkup_infra can belong to both MCU domain and the wkup domain depending on the use case. For the deep sleep low power mode, it is in WKUP domain. However, when the mcu domain is running safety use case, all the modules connect to CBASS_wkup_safe are in the MCU domain.

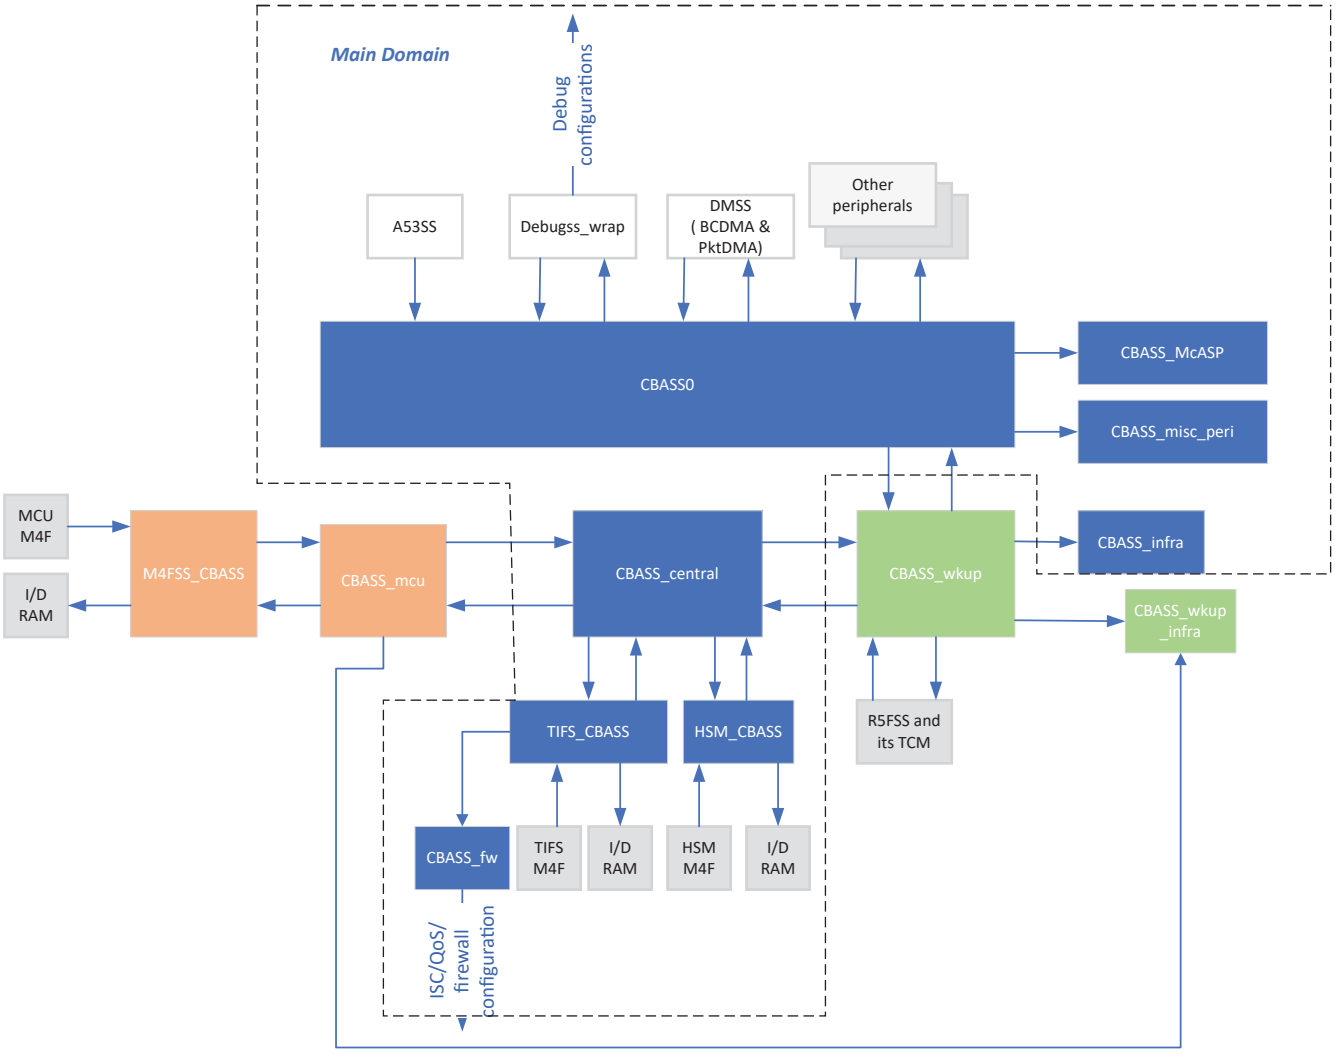

Figure 3-1. System Interconnect Overview

3.1.2 IO Coherency Support

There are 4 bits for Asel sideband signals, which enables a single SoC to support up to 16 different memory maps. Asel=0 is default to the regular SoC memory map, which CBASS is used for address decoding purpose. Non-zero Asel value is assigned to the target end point, which can be bypass the normal address decoding. All the transactions with asel 0 go through address decoding based on the address the transactions carry. However, the non-zero Asel value can be assigned to the transactions through either DMA configuration for both BCDMA and pktDMA transaction or through the QoS block inserted for each initiator interface. Asel value 14 and 15 are dedicated to route any transactions requiring IO coherency to A53SS's ACP interface. The transactions with Asel value 1-13 will be routed to the null end point for graceful termination.

Transactions with asel=14 and 15 are routed to ACP port

- Write transaction with Asel=14 causes A53SS L2 cache allocation: for cache warming feature
- Write transactions with Asel=15 does not cause A53SS L2 cache allocation
- Read transactions with Asel=14 and 15 does not cause L2 cache allocation
- All the transactions to ACP port can be protected by firewall if firewall is inserted by the SoC level CBASS

A53SS cluster checks security on the transactions from the ACP port. However, it does not have the supervisor and user mode check. If different permission is needed for supervisor and user mode transactions, the region-based firewall logic should be used to grant different access permission.

Copyright © 2024 Texas Instruments Incorporated

The transaction from the following processor do not have IO coherency support:

- HSM
- R5FSS in WKUP domain
- PRUSS-M
- MCU M4FSS

3.1.3 Timeout Gasket

In the system with mixture level of safety requirements, it is important to isolation the impact from the fault from the lower safety level spreading to the domain with higher safety level. When there are non-recoverable faults in the domain with lower safety level, the safety processor should either have the capability to diagnostic the fault and/or reset the fault components.

When the fault happens on the target interface side, the target time out gasket provides the capability to gracefully terminate the transactions and return error status back to the initiator, so the interconnect is not stalled due to the fault at the target side.

When the fault happens on the initiator interface side, the initiator time out gasket shall provide the capability to flush out all the pending transactions while prevent the fault initiator interface issues more transactions. It also has logic to track the idle state when all the pending transactions are completed. The IP can't be brought down or reset unless the initiator time out gaskets enters idle state. All the control mechanism for the initiator side time out gasket comes from chip level MMR. By default, the time out gasket is disabled. It requires safety processor to enable it.

All the time out gaskets assert interrupt when there are any time out happen, and those interrupts are routed to ESM and further routed to safety processor MCU M4FSS.

MCU M4FSS is designed to be a safety processor and it is responsible to manage all the time out events from the timeout gasket logic.

When MCU M4FSS is running safety application, the components connected to CBASS_MCU and CBASS_wkup_safe are part of the safety domain, which can be isolated from the rest of SoC. The timeout gaskets are inserted around CBASS_MCU and CBASS_wkup_safe to prevent the fault outside these two CBASS propagated into the safety domain.

Copyright © 2024 Texas Instruments Incorporated

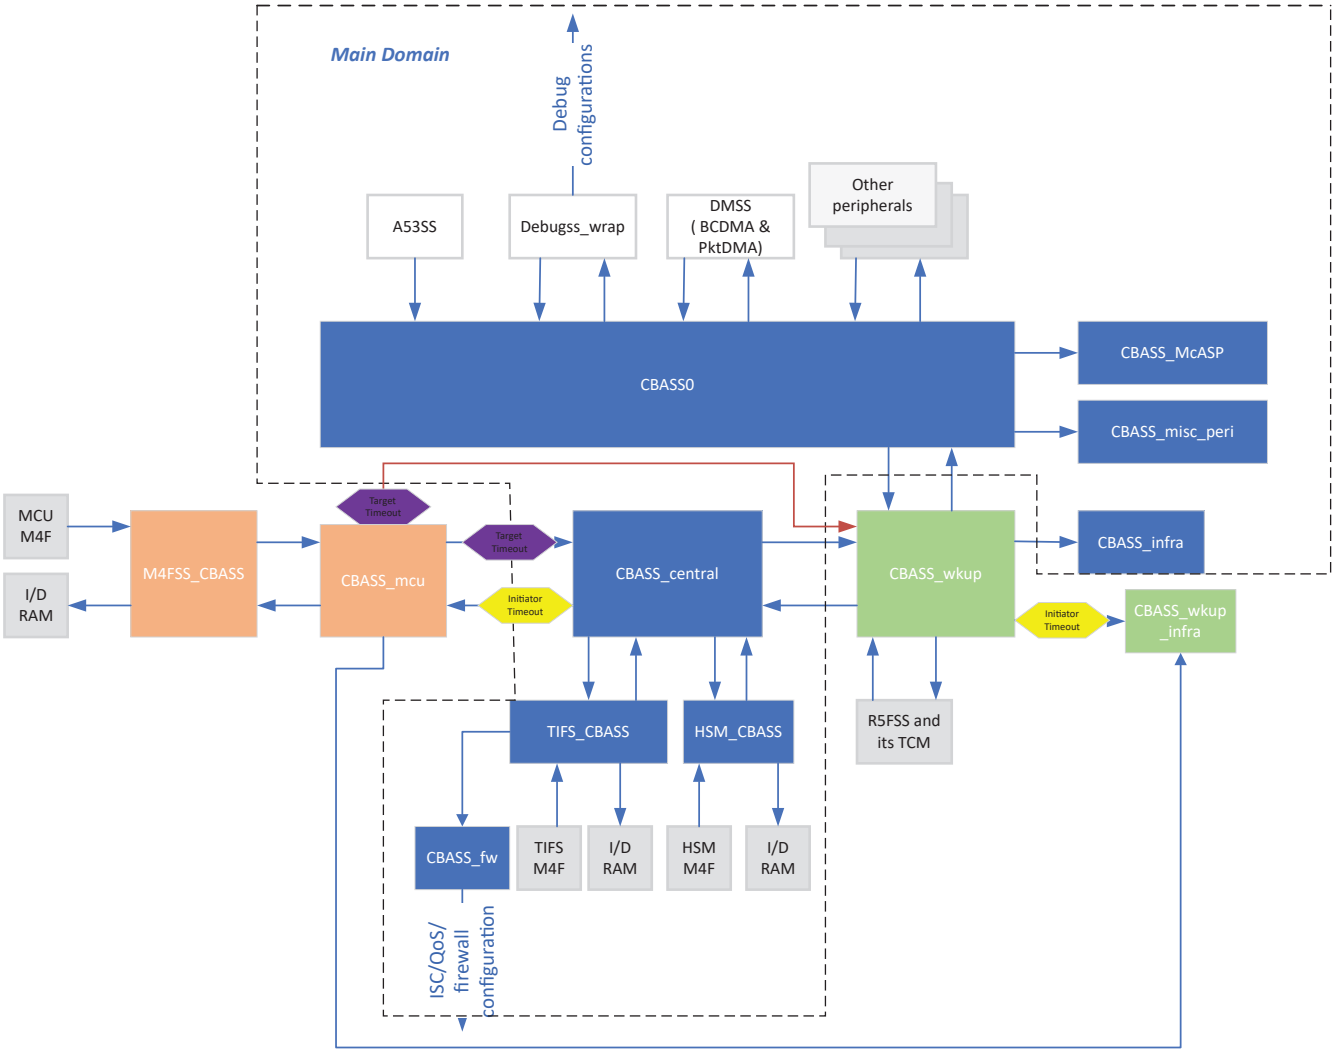

Figure 3-2. Timeout Module to Prevent Fault Propagation

- Target side time out gasket: it is inserted to protect the path from MCU M4FSS to access the end points outside safety domain. The configuration of the target side timeout module is done through a dedicated configuration interface.
- Initiator side time out gasket: it is inserted to protect the path from the initiator interfaces outside of the safety domain to access the safety domain (the modules connected to cbass_mcu and cbass_wkup_safe). If any fault outside the safety domain causes either data or status could no longer return back, the initiator timeout gasket can flush this data/status return to allow safety domain progress. This initiator gasket is reset when the domain it connects to goes through reset. The configuration of the initiator side timeout gasket is through the registers in mcu_ctrl_mmr.

By default, the timeout gasket is not enabled. Before MCU M4FSS runs safety application, MCU M4FSS needs to enable the timeout gasket functionality.

3.1.3.1 Software Sequence to Enable Timeout Gasket

MCU M4FSS shall be the only processor to enable the timeout gasket function.

The following software sequence shall be followed to enable the target timeout gasket inserted between cbass_mcu and cbass_central.

Copyright © 2024 Texas Instruments Incorporated

1. Check whether LPSC_mcu2main_ISO in mcu_psc is disable state or not. If this LPSC is not in the disable state, MCU M4FSS configures LPSC_mcu2main to be OFF.
2. After LPSC_mcu2main is in disable state,
   a. If main domain is under reset, MCU M4FSS waits until the main domain out of reset
   b. MCU M4FSS triggers a software flush to the target timeout gasket
3. MCU M4FSS configures mcu_PSC to enable LPSC_mcu2main_ISO. This allows the transactions from mcu domain can reach main domain.
4. MCU M4FSS enables target timeout gasket

The above SW sequence needs to be repeated to enable the target side timeout gasket inserted from cbass_mcu to cbass_wkup_dm path controlled by LPSC_mcu2DM_ISO

The following software sequence shall be followed by enabling the initiator side timeout gasket:

1. MCU M4FSS check whether LPSC_main2mcu_ISO is in disable state. If it is not in disable state, configure mcu_psc to put LPSC_main2mcu in disable state
2. Wait until LPSC_main2mcu_ISO in disable state (which means no pending transactions from main domain to mcu domain)
3. MCU M4FSS triggers a flush operation in initiator timeout gasket through mcu_ctrl_mmr
4. MCU M4FSS configure/enable initiator timeout gasket by defining proper timeout period through mcu_ctrl_mmr.
5. MCU M4FSS enables LPSC_main2mcu_ISO

The initiator side timeout gasket inserted between Cbass_wkup_dm and cbass_wkup_safe shall follow the similar steps.

3.1.4 Route ID Allocation

Each transaction in the system carries a 12 bits route ID value. The route ID is used by the CBASS to route return status/data back to transaction initiator. The transaction with the same route ID indicates the originator of the transaction in the system. And each originator of the transaction in the SoC has a unique route ID value. Route ID value is also used by ddr16ss to remap the arbitration priority inside ddr16ss.

Table 3-1. Route ID Table

Module Name	Initiator Interface	Which CBASS it is connected to	RouteID value	Able to access ACP port for IO coherency
A53SS	A53 core 0 non-cacheable read	cbass0	16	N

3.1.5 Quality of Service (QoS)

Majority of the initiator has a dedicated QoS block to provide the configurability of the transaction characteristic, such as orderID, priority/epriority, asel and etc.

OrderID is a 4 bits value, which is associated with each transaction. By default, all the transactions have orderID value set to 0x0. The orderID is used as a mechanism to load balance the traffic to DDR through two

Copyright © 2024 Texas Instruments Incorporated

parallel paths. The transactions with order ID 0-7 share one path, while transactions with 8-15 share a separate path. The OrderID value can be changed through QoS block for the initiators or through BCDMA and pktDMA configuration.

Each transaction in the system carries 3 bits priority information. The priority information is used for cbass for arbitration decision, which implements typical priority based round robin. Priority value 0x0 is the highest priority, while 0x7 is the lowest priority. By default, QoS has priority value set to 0x7(lowest priority).

Some of the modules such as DSS is able to adjust the priority of the transaction based on the system congestion condition. But majority of the transactions have static priority level set by the QoS block. But the priority setting through QoS block can be tuned to fit certain use case scenarios.

CAUTION

Priority, orderID and asel value from the QoS block shall only be modified as part of the initialization steps, when the SoC is idle. Changing the QoS block configuration during the run time is prohibited, and may cause system error or other undefined behavior.

Each QoS block has a unique identification, which is correspondent to the configuration address for that QoS block. If the QoS block's index is x, then the configuration address for that QoS block is 0x45D0_0000+ 1KB*x.

3.1.6 Initiator-Side Security Controls and Firewalls

Firewalls (FW) and Initiator-side Security Controls (ISC) are important interconnect components that enable hardware isolation for freedom from interference or security uses. ISCs enable every transaction to be identified and tagged to precisely assign the source ID. Firewalls are downstream (target) components that provide the ability to filtering transactions based on the sideband information.

The device protection depends on firewalls. They are used to protect data and configuration spaces by managing the accesses to these memory regions.There are two types of firewalls - region based and channelized. There are no channelized firewalls on system level. Only LPSC_SMS, LPSC_HSM_ISO, LPSC,_SA3_UL, LPSC_TIFS, and LPSC_HSM have channelized firewalls for MDCTL MMRs. Only region based firewalls are available on system level. See Section 3.1.6.2.1.1 and Section 3.1.6.2.2.1 for description of the region based and channelized firewalls.

On devices supporting secure boot, these components allow the SoC to support multi-tier security and provide segregation of secure and non-secure worlds. All configuration of ISCs and FWs are under exclusive control of Device Mamager, using a dedicated interconnect.

The number of ISC and Firewall blocks and placement of these blocks are based on the topology of each device. ISC and Firewall blocks are placed in host modules (AXI to VBUSM.C Bridge); or part of the interconnect (for example: CBASS).

Figure 3-3 presents a generic view of ISCs and Firewalls in SoC.

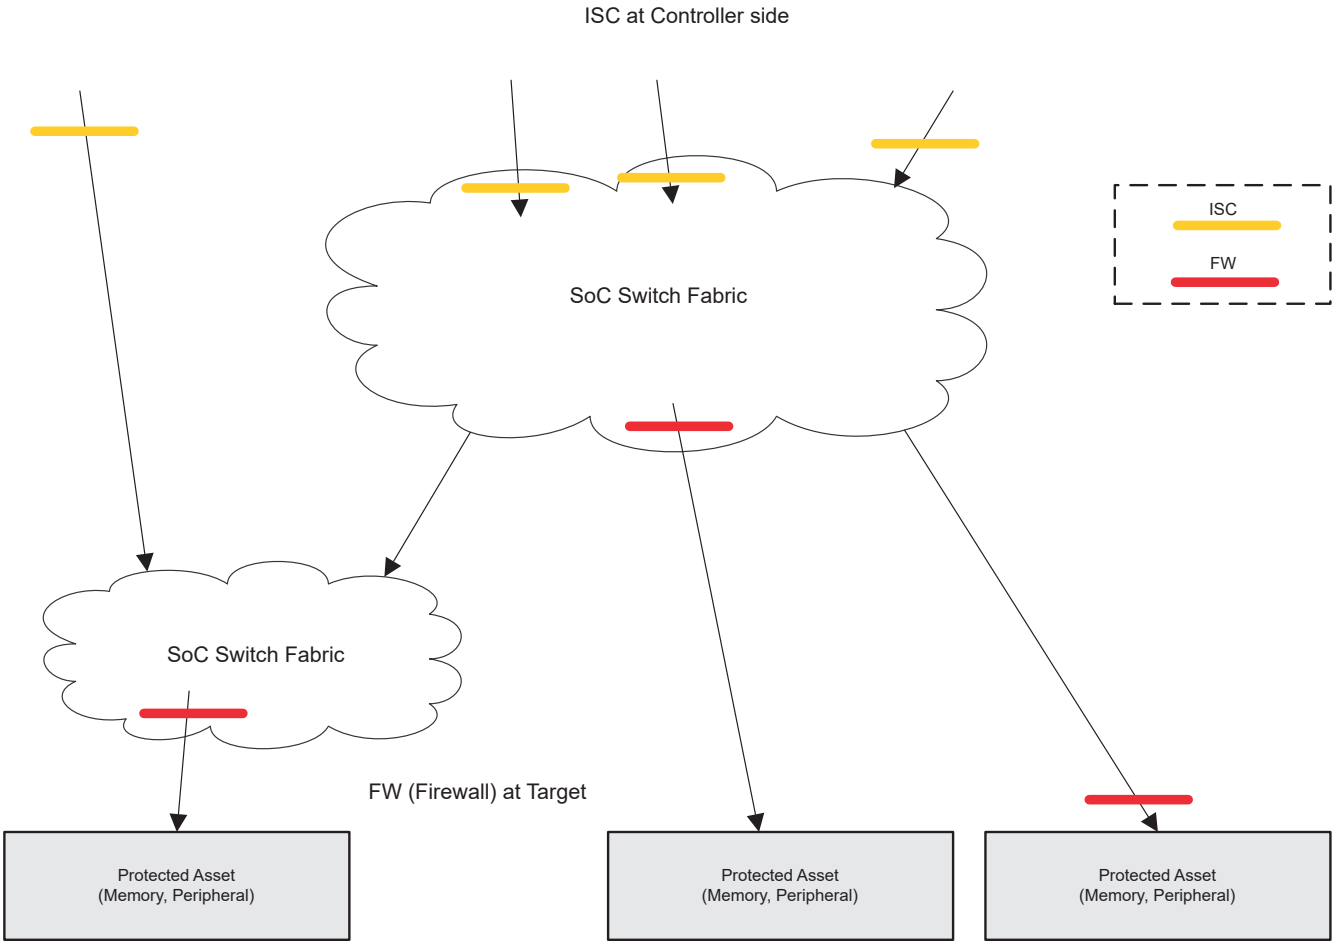

Figure 3-3. ISC and Firewall in SoC

Copyright © 2024 Texas Instruments Incorporated

3.1.6.1 Initiator-Side Security Controls (ISC)

Initiator-Side Security Control (ISC) modules are hosted at the initiator side where the transactions are sourced. ISC controls the security sideband attributes that are applied to outgoing transactions and have ability to override security values under exclusive control of the SMS.

ISC Capabilities:

- Attach Priv-ID to each bus transaction.
- Priv-ID is a source ID attached to identify the source of a transaction in the system.
- By default, each initiator in the system has a unique Priv-ID.
- Multiple modules can be assigned the same Priv-ID to form logical groups.
- Assert, De-assert or pass-through secure bit.
- Assert, De-assert or pass through Priv-bits.

ISCs are connected to the dedicated security VBUSP interconnect and can be exclusively configured by SMS. ISC optionally can support region and channel number based security control, where, based on incoming channel or address, the associated security controls, are applied.

Figure 3-4 presents ISC config registers per region.

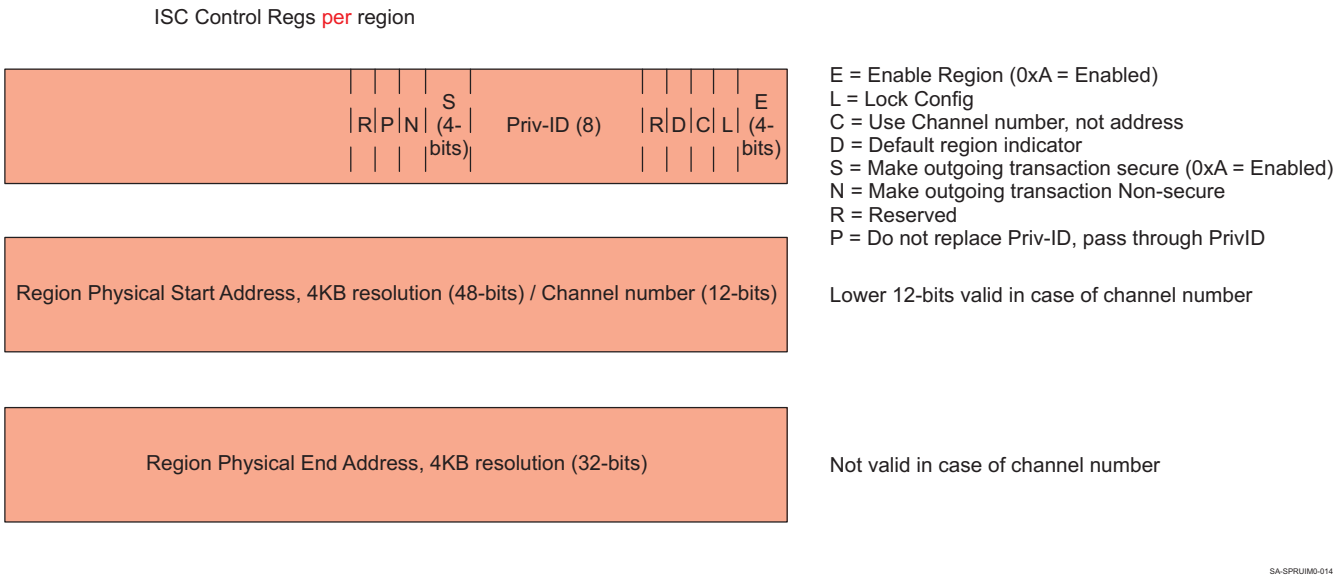

Figure 3-4. ISC Config Registers per Region

3.1.6.1.1 Priv-ID

Priv-ID is used to identify the logical source of transaction and is attached by ISC. The Priv-IDs are allocated based on subsystem as part of platform definition.

Table 3-3. Priv-ID

Inititator	Reset Priv-ID
COMPUTE_CLUSTER0	4
MCU_M4FSS0	100
MMCSD0	128
MMCSD1	129
MMCSD2	130
ICSSM0	138
SA3_SS0	152
GICSS0	154
USB0	155

Table 3-4. Special Priv-IDs (continued)

Special Priv-IDs	Hex Value	Decimal Value
Wild card Priv ID	0xC3	195
Block Priv ID	0xC5	197
DMA Reserved Priv-ID	0xC0	192

3.1.6.2 Firewalls (FW)

Firewalls play an important role in implementing overall SoC security by providing a means to allow or restrict access to device resources to any given controller entity or Secure/Non-Secure/Priv/User world. Firewalls are placed at various data path points throughout the SoC to control access to protected asset (Peripheral, memory and so forth).

Firewalls ensure that assets can be protected and are only accessible by allowed controller and in selected operation mode (Secure, Non-Secure, Priv, User, write, read and so forth). In case of firewall violations, the transaction is dropped and the appropriate violation code is registered with associated parameters.

There are three types of firewalls, Peripheral firewalls, Memory firewalls (referred as one group **Region Based Firewall** in the device-specific TRM) and Channelized firewalls.

Each Firewall module in the SoC has a unique Firewall ID that allows software to decode the source of each violation. The Firewall IDs are allocated based on subsystem as part of platform definition. The full SoC view of Firewall IDs for various Firewall modules are captured in Section 3.1.6.2.1.2.

3.1.6.2.1 Region-based Firewalls

Region-based firewalls are designed to protect peripherals, Memory (SRAM/DDR and so forth) and data regions (GPMC and so forth). Region-based firewalls have a defined firewall region count so that the peripheral/memory can be partitioned into multiple firewall regions.

Region-based firewalls can have either 1 or 3 Priv-ID slots per region, with associated permissions. The number of Priv-ID slots is determined based on placement of firewall block. Each region in this type of firewall is defined by a physical start and end address.

Figure 3-5 presents Region-based firewall config registers with 3 Priv-ID slots per region.

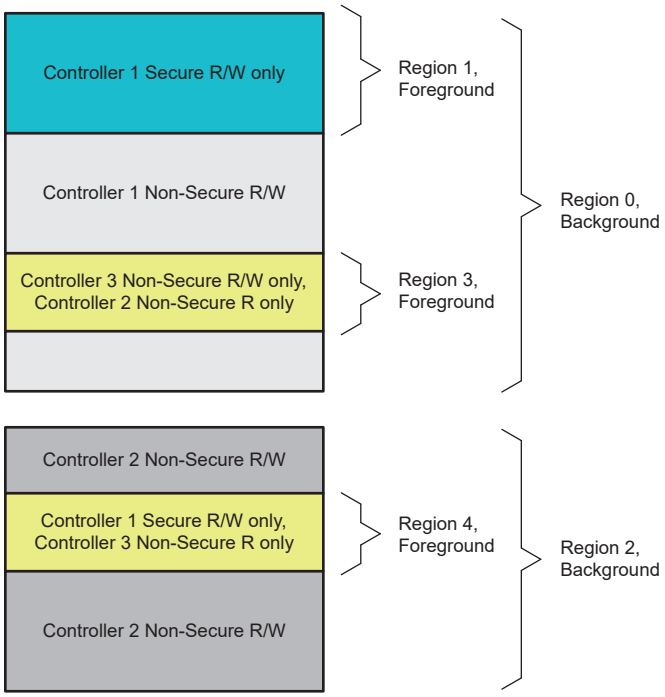

Figure 3-7. Firewall Regions

The Region-based firewall is configured using dedicated VBUSP port to CBASS/AXI to VBUSM.C Bridge/DRU that connects to the SMS private VBUSP interconnect.

3.1.6.2.1.1 Region Based Firewall Functional Description

The region based firewall provides a memory region based protection and isolation mechanism. For each defined memory region, it checks the transaction attributes such as secure vs non-secure, debug vs non-debug, supervisor vs user mode, read vs write and so on. The transaction is dropped, if it does not match the configuration and appropriate violation code is registered with offending parameters.

Host modules (for example, AXI2VBUSMC bridge or CBASSes) provide transaction attributes that are checked by the firewalls, which then determine if the transaction should be blocked or passed. The firewall implements filtering algorithm that compares these host incoming transaction parameters against the region policy to give block indication to the host. Firewall region registers configure the filtering mechanism which includes setting region address range, region permission registers and region control register. There are also firewall exception registers used for violation reporting and logging.

The region based firewall supports multiple regions. Each one is defined by address range and associated access permission. The minimum memory region size is 4KB. The firewall concurrently checks the incoming transaction against all enabled regions looking for violations.

Each firewall is associated with the following registers:

- CBASS_FW_REGION_i_CONTROL
- CBASS_FW_REGION_i_PERMISSION_0 to CBASS_FW_REGION_i_PERMISSION_2
- CBASS_FW_REGION_i_START_ADDRESS_L and CBASS_FW_REGION_i_START_ADDRESS_H
- CBASS_FW_REGION_i_END_ADDRESS_L and CBASS_FW_REGION_i_END_ADDRESS_H

Each region is defined by start and end physical address and associated permission and control registers. A firewall can have 1-24 regions. In case there is more than 1 region, then these registers are duplicated for all regions. Setting the CBASS_FW_REGION_i_CONTROL[3-0] ENABLE field to 0xA enables the region and makes firewall check active for this region. Setting to 0x1 the CBASS_FW_REGION_i_CONTROL[8] BACKGROUND bit indicates to the firewall that the region is background region. Setting to 0x1 the CBASS_FW_REGION_i_CONTROL[9] CACHE_MODE bit

Copyright © 2024 Texas Instruments Incorporated

ignores cacheable check, so that it cannot fail. In this case the access check is performed based on the READ and WRITE bits in CBASS_FW_REGION_i_PERMISSION_x. Clearing CACHE_MODE enables the cacheable check, so that cacheable transactions are allowed only when the corresponding cacheable permission bit (CBASS_FW_REGION_i_PERMISSION_x [y_CACHEABLE]) is set. If the CBASS_FW_REGION_i_CONTROL[4] LOCK bit is set to 0x1, then the region configuration cannot be changed at all. This is one-time change. This bit is typically used for primary controller to consume and lock its resources and then pass firewall control to secondary controller.

In case two regions overlap, the CBASS_FW_REGION_i_CONTROL[8] BACKGROUND bit is used to select the appropriate permission to be used. The region whose BACKGROUND bit is 0x0 (foreground) takes precedence and its permissions are taken into effect. The background region is ignored.

Note

There can be only one background region per firewall. Foreground regions can have overlapping addresses only with the background region.

It is a software mistake to have overlapping regions with the BACKGROUND bit set to the same value (either background or foreground). Software must be careful to not configure two overlapping regions with the BACKGROUND bit set to the same value.

The firewall also checks if the transaction crosses a 4KB boundary. If so, the transaction is blocked regardless of any matching regions.

When a region is set to be debugable through the corresponding CBASS_FW_REGION_i_PERMISSION_x [y_DEBUG] bit, the firewall ignores the read and write checks for any debug transactions, so that it cannot fail. This allows debug breakpoints to be written out to code even in read-only regions.

When a region is set to be cacheable through the corresponding CBASS_FW_REGION_i_PERMISSION_x [y_CACHEABLE] bit and CACHE_MODE = 0x0, the firewall ignores the read and write checks for any transaction (cacheable or not), so that it cannot fail due to these checks. This allows a write allocated cache to read a cache line even in write-only regions. Due to caches not protecting user and supervisor data from each other, the firewall allows cacheable access to the region when either the user cacheable permission or the supervisor cacheable permission is set.

The firewall notifies the host that the transaction is blocked in case of the following violation conditions:

- All regions are disabled.
- Incoming address does not hit any region.
- Non-secure incoming read transaction attempting to access configured secure-only write/read region.
- Non-secure incoming write transaction attempting to access configured secure-only write/read region.
- Secure incoming read transaction attempting to access configured non-secure-only write/read region.
- Secure incoming write transaction attempting to access configured non-secure region.
- Incoming secure write transaction attempting to access configured secure read region. This check is ignored if the region is configured as cacheable.
- Incoming secure read transaction attempting to access configured secure write region. This check is ignored if the region is configured as cacheable.
- Incoming non-secure write transaction attempting to access configured non-secure read region. This check is ignored if the region is configured as cacheable.
- Incoming non-secure read transaction attempting to access configured non-secure write region. This check is ignored if the region is configured as cacheable.
- Incoming non-secure debug access to non-debugable secure region.
- Incoming non-secure debug access to non-debugable non-secure region.
- Incoming secure debug access to non-debugable secure region.
- Incoming secure debug access to non-debugable non-secure region.
- Incoming cacheable transaction attempting to access non-cacheable configured region.

Copyright © 2024 Texas Instruments Incorporated

All violation parameters caused the exception are logged in the firewall exception registers described in *Firewall Exception Registers*. Table 3-5 shows the mapping between the register fields and violation parameters. If the CBASS_EXCEPTION_LOGGING_CONTROL[0] DISABLE_F bit is set to 0x1, logging is disabled.

If violation occurs, the corresponding firewall notifies the Security Manager (SMS) driving high a dedicated signal. The notification (that is, the signal) can be masked by setting to 0x1 the CBASS_EXCEPTION_LOGGING_CONTROL[1] DISABLE_PEND bit. The firewall exception notification signal gets automatically cleared when the CBASS_EXCEPTION_LOGGING_DATA3 register is read. That signal can be manually set via the CBASS_EXCEPTION_PEND_SET[0] PEND_SET bit and cleared via the CBASS_EXCEPTION_PEND_CLEAR[0] PEND_CLR bit. Reading one of these two bits returns the status of the signal (that is, violation occurred or not).

Table 3-5. Firewall Violation Parameters

Field	Value	Description
CBASS_EXCEPTION_LOGGING_HEADER0[31-24] TYPE_F	0x1	Exception type for firewall violation. This is fixed for the SoC firewalls and is used by software to detect that this corresponding violation comes from a firewall.
CBASS_EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID	0x-	Firewall ID. Unique for each firewall. This is used to identify the exact firewall that issued violation so that software detects the precise source.
CBASS_EXCEPTION_LOGGING_HEADER0[7-0] DEST_ID	0x-	Destination ID of node where the firewall violation has be to routed.
CBASS_EXCEPTION_LOGGING_HEADER1[31-24] GROUP	0x0	Exception group. This is used to group exceptions to category. All firewall exceptions are in one group.
CBASS_EXCEPTION_LOGGING_HEADER1[23-16] CODE	Exception code:	
	0x0	Reserved.
	0x1	No region enabled.
	0x2	Incoming address does not hit any active region and transaction is dropped.
	0x3	Reserved.
	0x4	Cacheable error. A cacheable transaction attempting to read/write non-cached marked region.
	0x5	Debug error. A debug transaction attempting to read/write a non-allowed debug region.
	0x6	Read error. A Read transaction attempting to read from non-allowed read region.
	0x7	Write error. A Write transaction attempting to write from non-allowed write region.
	0x8	4KB crossing error. A transaction attempting to cross a 4KB boundary.
CBASS_EXCEPTION_LOGGING_DATA0[31-0] ADDR_L	0x-	Lower 32 address bits (31:0) of the incoming transaction
CBASS_EXCEPTION_LOGGING_DATA1[15-0] ADDR_H	0x-	Upper 16 address bits (47:32) of the incoming transaction

3.1.6.2.2 Channelized Firewalls

A Channelized firewall is designed to protect modules that have logical channels (Ring Accelerator and so forth, for example). These firewalls operate at the resolution of a channel and have no association with physical addresses. Each channel is defined as a logical control entity.

In case of channelized firewalls, the number of regions are less than or equal to number of logical channels and each typical channel/region is very small memory space (typically in Bytes, like 16 bytes). A channel is owned by one processing entity, hence only 1 Priv-ID slot is provided for each Channelized firewall along with associated permissions.

Copyright © 2024 Texas Instruments Incorporated

Figure 3-8 presents Channelized firewall config registers with 1 Priv-ID slot per region.

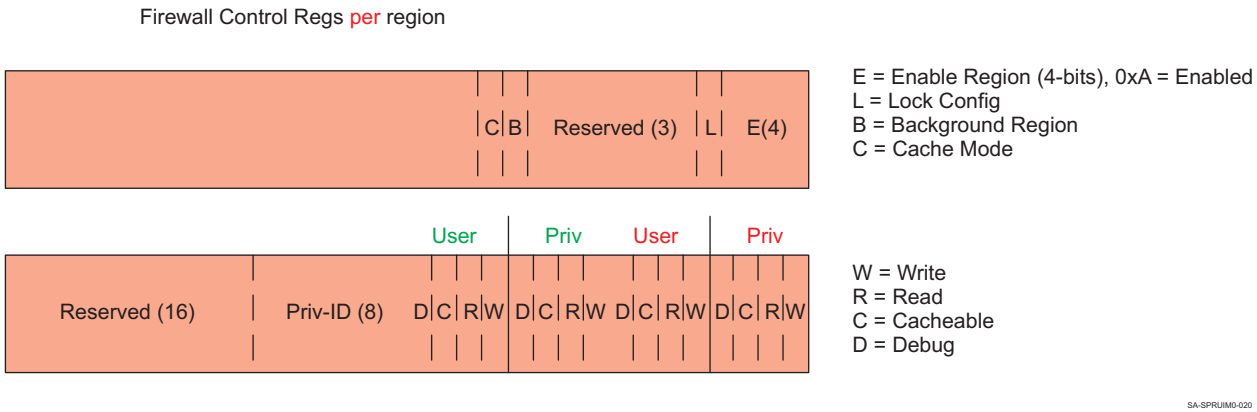

Figure 3-8. Channelized Firewall Config Registers with 1 Priv-ID slot per Region

The Channelized firewall is configured using dedicated VBUSP port to CBASS/Bridges that connects to the Device Manager private VBUSP interconnect.

Note

For more information about the interconnect firewalls, see *Interconnect Firewalls*.

3.1.6.2.2.1 Channelized Firewall Functional Description

The channelized firewall protects an address space that consists of multiple channels where each channel needs its own permissions. This is in contrast to the region based firewall which implements a number of regions that can protect a programmed address range. The channelized firewall extends this to a larger number of ranges that can be protected, but each range is no longer programmable and is instead fixed to a particular channel address range. This allows each channel to be owned and protected individually. The channels within same memory region have same size. The system can allocate each channel to a particular owner or owner groups with certain permissions and guarantee that others cannot access that channel. This protection is useful for either accessing data resources, or control for each resource. The channelized firewall provides an efficient way to implement access protection and isolation requiring finer granularity than the region based firewall.

Same as the region based firewall, the channelized firewall may also support multiple regions. Each region contains a number of channels that need to be protected individually and has size in bytes equal to the channel's data to protect. This allows multiple regions so that the firewall can protect a module containing multiple sets of registers that are each channelized and need separate protections, such as data access as well as control setup.

The transaction addresses are compared against region addresses to identify which region is being accessed. Then the offset within the region is used to identify the particular channel being accessed. If a valid channelized region is not decoded during the firewall check, then the transaction is passed through unmodified because the module may have other regions which are not channelized, but accesses to them are already protected by a region based firewall so the channelized one should not block them.

The permission check is performed just like for a region based firewall. The channelized firewall checks for user or supervisor priviledge levels. It also checks for transactions that cross important boundaries and gives errors if violated. The first check is for a transaction crossing a 4KB address boundary. This is illegal on the bus, so the firewall checks for compliance. The second check is if the transaction crosses a channel boundary. The channelized firewall blocks a transaction accessing multiple channels in the same burst, as it cannot check the permission for the entire range of channels. The channelized firewall also supports error logging when a transaction fails the checks. It sends information about the type of error and the transaction that caused it.

The channelized firewall is associated with the following registers:

Copyright © 2024 Texas Instruments Incorporated

- *_CH_i_CONTROL, where "i" can be from 0 to 63 and denotes the channel.
- *_ CH_i_PERMISSION_x, where "i" can be from 0 to 63 and denotes the channel and "x" can be 0 to 2.

Table 3-7. Channelized Firewall Configuration

Channelized Region	which register inside PSC0 is protected
0	MDCTL27 register inside PSC0 to control LPSC_SMS_common
2	MDCTL30 register inside PSC0 to control LPSC_HSM
3	MDCTL31 register inside PSC0 to control LPSC_Sa3ul
4	MDCTL32 register inside PSC0 to control LPSC_HSM_ISO

3.1.7 Interconnect Error Reporting Feature

CBASS routes the transaction to null end point for graceful termination under the following situation:
- There is no physical connection between initiator and target end points
- Or target interface is in disabled state
- Or the transaction is sent to an unpopulated address

The null end point returns the error status back to the initiator to prevent the interconnect hang. At the same time, CBASS module logs this transaction information in err_reg region and issues an error interrupt (default_err_intr). This default_err_intr is sent to all the application processors for debug purpose.

If the transaction is sent to a valid target interface, however the firewall in front of the target interface can prohibit the transaction, the transaction will be logged in the glb_regs region and cbass will assert a default_exp interrupt.

3.1.8 Connectivity Table

Whether an initiator can access certain target or not depends on following factors:
- Whether there is a physical connection between the initiator and the target end point, which is identified with unique memory address.
- For MCU MCUSSand R5FSS: those native 32bit processors have slightly different memory map view. And RAT block may need to be programmed to be able to access some target endpoints
- Majority of the target end points are protected by firewall. The firewall needs to be proper configured to make sure that transactions from the initiator can reach the final target end point.

Table 3-8 shows the physical connectivity between initiator and the target end points.

3.1.9 QoS Programming Guide

The QoS MMR is integrated as part of data plane CBASS to provide programmability of priority, orderID and CoS sideband signals for each initiator port in the data plane. Currently CoS sideband signal is not used for any routing or schedule purpose. For most of the initiator ports, it has only one setting of the orderID and CoS field. For the initiator port supports with multiple channels, the transactions in each channel can be programmed to have different sets of priority, orderID and CoS. The orderID is a four-bit field value. All the transactions coming from the same initiator ports with the same orderID expect to receive the read data in order.

In the previous generation of the CBASS, how the traffic is split among parallel paths to the same end points is hard coded. The traffic from a certain initiator port is hard coded to choose one of the parallel paths. Due to the nature of hard coded, the system can't do load balancing based on the use case. Keystone3 removes this limitation through splitting traffic using OrderID value. Since the orderID value for the traffic from each initiator port is programmable, the user can load balance based on the use case scenario.

Each target port in each SCR has its own arbiter. The SoC CBASS arbitration is based on epriority. For the ports with equal epriority, the arbiter uses round robin to break the tie.

DDR EMIF also uses orderID to maintain transaction ordering. All the transactions with the same orderID sent to EMIF will be executed in order. In order to maximize the EMIF performance, user shall carefully use the full range of 16 orderID values. Therefore, EMIF can utilize its re-ordering mechanism to improve the EMIF utilization.

Inside EMIF controller, there are mapping register to map CBA priority to AXI priority. EMIF controller schedule transaction using strict priority scheme based on AXI priority. In order to maximize the DDR utilization to reduce the memory page open/close and read and write turn around penalty, it is suggested to map to a single AXI priority.

AM62 has two real-time peripherals DSS and CSI_RX, both of them have real time deadline. DSS has internal mflag, which can be used to change the priority level of the transaction based on the FIFO depth. CSI_RX is serviced by block copy DMA. In order to maintain the CSI_RX bandwidth to prevent CSI_RX data overflow, the high performance DMA block channel shall be used to issue up to 512B write data to DDR. In addition, the priority for the block copy DMA channel shall use the highest priority.

Copyright © 2024 Texas Instruments Incorporated

In addition, GPU can burst out a long back to back burst of transactions to completely exhaust the DDR bandwidth. In order to mitigate the risk of missing real-time peripheral deadline, bandwidth limiters are added to AM62 to control the transactions from both GPU and A53. User can configure and tune the bandwidth limiter parameters based on the use cases.

3.1.10 Performance Considerations

3.1.10.1 Initiator Timeout Gasket

In the normal condition, the initiator gasket does not add additional latency to the transaction. However, if the score board which tracks the pending transaction is full, the transaction may be temporarily stalled until the previous transactions are returned.

3.1.10.2 Target Timeout Gasket

Target side gasket adds latency on both forward path and return paths. On the forward path, one cycle latency is added for each command. If it is a write transaction, it also adds one cycle for the write data. On the response path, additional 2 cycles are added for read return data and 2 cycles added on write status return. In addition, the target timeout gasket also stalls the transaction if there is no free slot in the scoreboard for tracking pending transactions:

- If a write command comes in and there are no free slots in the write scoreboard, the entire command bus and write data bus will stall
- If a read command comes in and there are no free slots in the read scoreboard, the entire command bus will stall

If the target timeout gasket enters the time out condition:

- If a write transaction is being timed out, then the write status bus will stall while the write scoreboard flushes the command
- If a read transaction is being timed out, then the read data bus will stall while the read scoreboard flushes the command

Therefore, the target timeout gasket shall be configured properly to avoid stalls due to lack of scoreboard.
In addition, all the target side time out gaskets are for VBUSM interface. If a VBUSP target interface needs isolation, it requires a M2P bridge added, which future increases the latency.

3.1.10.3 Latency Introduced by Auto Clock Gating Control

Auto clock gating feature is also called nogate control. It is a technique to reduce the dynamic power for SoC. When nogate control is set to 1b0, it means that the CBA clock will be automatically shut off after 12 cycles idle. After the clock is auto shut off, the first future transaction will have additional pipe latency for each hop. The subsequence transaction will not have this latency penalty if it is arrived within 12 clock cycle windows. When nogate control is set to 1b1, the CBA clock will not shut off automatically.

The auto clock gating control can be modified during device initialization time through register CLKGATE_CTRL in wkup_ctrl_mmr block.

4.1.1 DDR16 Subsystem (DDR16SS)

This section contains the integration details for the 16-bit DDR module on this device. For Further information, see the DDR16 Subsystem (DDR16SS) section of the Processors and Accelerators chapter

4.1.1.1 DDR16SS Not Supported Features

The following features are not supported on this family of devices:

- DDR3, DDR3L, DDR3U, and LPDDR4x Devices
- ½ width (8-bit) mode
- DIMMS
- Data bus obfuscation / data encryption
- Automatic periodic scrubbing of SDRAM for ECC
- Address range of greater than 8GBytes for DDR4
- Address range of greater than 4GBytes for LPDDR4
- memory devices with more than 17 row address bits
- LPDDR4 devices with byte mode die configurations

4.3.2 Spinlock

This section contains the integration details for the Spinlock module on this device. For Further information, see the Spinlock section of the Peripherals chapter

4.3.2.1 SPINLOCK Unsupported Features

The following features are not supported on this family of devices:

- ARM Architectural Spinlock Instructions (LDREX,STREX)
- Any use model other than binary mutex (ex. counting semaphore, lockless programming) - Spinlock MMR is a single binary 0,1 implemented by a state machine
- 64 bit accesses - Spinlock MMRs are aligned on 32-bit boundaries meaning a 64 bit access affects the state of 2 spinlocks

4.3.2.2 Module Allocations

Table 4-25. Spinlock Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main

4.5.2 Peripheral DMA (PDMA)

This section contains the integration details for the PDMA module on this device. For Further information, see the Peripheral DMA (PDMA) section of the Data Movement Architecture chapter

4.5.2.1 PDMA Unsupported Features

The following features are not supported on this family of devices:

- Dynamic Transfer Requests
- Cross-Channel Triggering

Copyright © 2024 Texas Instruments Incorporated

4.6 Audio

4.6.1 Multichannel Audio Serial Port (MCASP)

This section contains the integration details for the McASP module on this device. For Further information, see the Multichannel Audio Serial Port (MCASP) section of the Peripherals chapter

4.6.1.1 MCASP Unsupported Features

The following features are not supported on this family of devices:

- Muting output (AMUTE)
- Muting input (AMUTEIN)
- Instances may not support all pin options. See device specific datasheet for details on which McASP instance support which pins

4.6.1.2 Module Allocations

4.7 General Connectivity

4.7.1 General Purpose Input/Output (GPIO)

This section contains the integration details for the GPIO modules on this device. For Further information, see the General Purpose Interface section of the Peripherals chapter

4.7.1.1 GPIO Unsupported Features

The following features are not supported on this family of devices:

- The following apply to MCU_GPIO0:
  - MCU_GPIO0_[143:24] are not pinned out.
  - Interrupts [143:24] are not pinned out.
  - Bank Interrupts [8:2] are not pinned out.
- The following apply to GPIO0:
  - GPIO0_[143:92] are not pinned out.
  - Interrupts [143:92] are not pinned out.
  - Bank Interrupts [8:6] are not pinned out.
- The following apply to GPIO1:
  - GPIO1_[143:72] are not pinned out.
  - Interrupts [143:72] are not pinned out.
  - Bank Interrupts [8:5] are not pinned out.

4.7.1.2 Module Allocation

Table 4-47. GPIO Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main
GPIO0			✓
GPIO1			✓
MCU_GPIO0		✓	

4.7.1.3 Resets, Interrupts, and Clocks

Table 4-48. GPIO Integration Attributes

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	dependences
GPIO0	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_ALWAYSON	0	ON	NO	NONE

4.7.2 Inter-Integrated Circiuit (I2C)

This section contains the integration details for the I2C module on this device. For Further information, see the Inter-Integrated Circiuit (I2C) section of the Peripherals chapter

4.7.2.1 I2C Unsupported Features

The following features are not supported on this family of devices:

- Serial Camera Control Bus (SCCB) Protocol
- DMA Mode
- Full I^2C electrical compliance for I2C modules using device pins with LVCMOS voltage buffers (Refer to chapter 4 of the device-specific Datasheet for details related to device *Terminal Configuration and Functions*)
- High-speed (3.4-Mbps) operation for I2C modules using device pins with LVCMOS voltage buffers (Refer to chapter 4 of the device-specific Datasheet for details related to device *Terminal Configuration and Functions*)
- Debug suspend mode
- Asynchronous wakeup (via IO Daisy Chain) not supported by Main domain instances.

4.7.2.2 Module Allocations

Table 4-52. I2C Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main
I2C0			✓
I2C1			✓
I2C2			✓
I2C3			✓
MCU_I2C0		✓

4.7.3 Multichannel Serial Peripheral Interface (MCSPI)

This section contains the integration details for the MCSPI module on this device. For Further information, see the Multichannel Serial Peripheral Interface (MCSPI) section of the Peripherals chapter

4.7.3.1 SPI Unsupported Features

The following features are not supported on this family of devices:

- Peripheral mode wakeup.
- Retention During Power Down

4.7.3.2 Module Allocations

Table 4-57. MCSPI Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main
MCSPI0			✓
MCSPI1			✓
MCSPI2			✓
MCU_MCSPI0		✓	
MCU_MCSPI1		✓	

4.7.3.3 Resets, Interrupts, and Clocks

Table 4-58. MCSPI Integration Attributes

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	dependences
MCSPI0	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_IP	34	ON	YES	LPSC_DM2MAIN_INFRA_ISO
MCSPI1	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_IP	34	ON	YES	LPSC_DM2MAIN_INFRA_ISO

4.7.4 Universal Asynchronous Receiver/Transmitter (UART)

This section contains the integration details for the UART module on this device. For Further information, see the Universal Asynchronous Receiver/Transmitter (UART) section of the Processors and Accelerators chapter

4.7.4.1 UART Unsupported Features

The following features are not supported on this family of devices:

- 12Mbps not supported for MCU and WKUP domains.
- Full modem handshaking is not available on all instances. See device datasheet for instances supporting full modem handshaking.
- Synchronous mode - SCLK not pinned out
- ISO7816 Mode
- SCR DMA Mode 2
- Multi-drop Transmission
- 9-bit Mode

4.7.4.2 Module Allocations

Table 4-62. UART Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main
UART0			✓
UART1			✓
UART2			✓
UART3			✓
UART4			✓
UART5			✓
UART6			✓
MCU_UART0		✓	
WKUP_UART0	✓		

4.7.4.3 Resets, Interrupts, and Clocks

Table 4-63. UART Integration Attributes

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	dependences
MCU_UART0	WKUP_PSC0	PD_M4F	LPSC_MCU_COMMON	9	ON	YES	LPSC_DM2SAFE_ISO

4.8 High-speed Serial Interfaces

4.8.1 Gigabit Ethernet Switch (CPSW)

This section contains the integration details for the CPSW module on this device. For Further information, see the Gigabit Ethernet Switch (CPSW) section of the Peripherals chapter

4.8.1.1 CPSW Unsupported Features

The following features are not supported by the CPSW switch:

- Maximum frame size of 9600 bytes
- GMII Mode
- SGMII Mode
- MACSEC
- Synchronous Ethernet

4.8.1.2 Module Allocations

4.8.2 Universal Serial Bus Subsystem (USB)

This section contains the integration details for the USB module on this device. For Further information, see the Universal Serial Bus Subsystem (USB) section of the Peripherals chapter

4.8.2.1 USB2SS Unsupported Features

The following features are not supported on this family of devices:

- Battery Charger Support
- Accessory Charger Adaptor Support
- On-The-Go (OTG)
- No Virtualization Support
- SuperSpeed (5Gb/s) operation
- USB 2.0 ECN: Link Power Management (LPM)
- Low Speed operation in device mode
- Charger Detection

4.9.5 Multimedia Card Secure Digital (MMCSD)

This section contains the integration details for the MMCSD module on this device. For Further information, see the Multimedia Card Secure Digital (MMCSD) section of the Peripherals chapter

4.9.5.1 MMCSD Unsupported Features

The following features are not supported on this family of devices:

- The following apply to 4-bit MMCSD instances:
  - SD Card busy LED - Not pinned out
  - High Speed DDR
- The following apply to 8-bit MMCSD instances:
  - SD Card busy LED - Not pinned out
  - SD/SDIO/MMC Cards (Removable) - no support for 4-pin/8-pin muxing
  - SD Card Detect Pin - Not pinned out
  - SD Card Write Protect Pin - Not pinned out
  - High Speed DDR

4.10 Industrial and Control Interfaces

4.10.1 Modular Controller Area Network (MCAN)

This section contains the integration details for the MCAN module on this device. For Further information, see the Modular Controller Area Network (MCAN) section of the Peripherals chapter

4.10.1.1 MCAN Unsupported Features

- Debug DMAs - DMA Ack not supported by PDMA architecture. Debug messages can be traced through the RX FIFO.
- TX DMA channels 3-31 are not supported by the Main domain instance (MCAN0)- Only TX_DMA[2:0] have associated PDMA channels
- DMA is not supported on the MCU domain instances, MCU_MCAN0 and MCU_MCAN1

4.10.1.2 Module Allocations

Table 4-102. MCAN Modules Allocation within Device Domains

4.11 Camera Subsystem

4.11.1 Camera Serial Interface Receiver (CSI_RX_IF)

This section contains the integration details for the CSI_RX_IF module on this device. For Further information, see the Camera Serial Interface Receiver (CSI_RX_IF) section of the Peripherals chapter

4.11.1.1 CSI_RX_IF Unsupported Features

The following features are not supported on this family of devices:

- Line Count Error Interrupt (Streams 1-3)
- Frame Mismatch Error Interrupt (Streams 1-3)
- Frame Count Error Interrupt (Streams 1-3)
- FCC Stop Interrupt (Streams 1-3)
- FCC Start Interrupt (Streams 1-3)
- Line/Byte Interrupt (Streams 1-3)
- Timer / Timer Interrupt (Streams 1-3)
- VID32 Streams to VPAC, no VPAC available
- PPI Retransmission, No Transmit interface available

4.12.2 Real Time Interrupt (RTI)

This section contains the integration details for the RTI module on this device. For Further information, see the Real Time Interrupt (RTI) section of the Peripherals chapter

4.12.2.1 RTI Unsupported Features

The following features are not supported on this family of devices:

- Analog watchdog timer
- External clock supervision
- Periodic Interrupt
- Timestamp (Capture Registers)

4.12.2.2 Module Allocations

Table 4-137. RTI Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main
RTI4			✓
RTI0			✓
RTI1			✓
RTI2			✓
RTI3			✓
MCU_RTI0		✓	
WKUP_RTI0	✓		

4.12.2.3 Resets, Interrupts, and Clocks

4.13 Internal Diagnostic Modules

4.13.1 Dual Clock Comparator (DCC)

This section contains the integration details for the DCC module on this device. For Further information, see the Dual Clock Comparator (DCC) section of the Peripherals chapter

4.13.1.1 DCC Unsupported Features

The following features are not supported on this family of devices:

- There are no unsupported features

4.13.1.2 Module Allocations

Table 4-152. DCC Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main
DCC0			✓
DCC1			✓
DCC2			✓
DCC3			✓
DCC4			✓
DCC5			✓
DCC6			✓
MCU_DCC0		✓	
MCU_DCC1		✓	

4.13.1.3 Resets, Interrupts, and Clocks

Table 4-153. DDC Integration Attributes

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	dependences
DCC0	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_ALWAYSON	0	ON	NO	NONE
DCC1	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_ALWAYSON	0	ON	NO	NONE
DCC2	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_ALWAYSON	0	ON	NO	NONE
DCC3	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_ALWAYSON	0	ON	NO	NONE
DCC4	PSC0_PSC_0	GP_CORE_CTL	LPSC_MAIN_ALWAYSON	0	ON	NO	NONE

4.13.2 Error Signaling Module (ESM)

This section contains the integration details for the ESM module on this device. For Further information, see theError Signaling Module (ESM) section of the Peripherals chapter

4.13.2.1 ESM Unsupported Features

The following features are not supported on this family of devices:

- No Dedicated ERROR Pin for MAIN domain ESM. MAIN ESM error interrupts are routed to the MCU ESM - the MCU ESM drives the MCU_ERROR pin and can factor in errors from MAIN ESM if programmed to do so.

4.13.2.2 Module Allocations

Table 4-165. ESM Modules Allocation within Device Domains

Instance	Domain		
	WKUP	MCU	Main
ESM0			✓
WKUP_ESM0	✓		

4.13.2.3 Resets, Interrupts, and Clocks

Table 4-166. ESM Integration Attributes

4.13.3 Memory Cyclic Redundancy Check (MCRC64)

This section contains the integration details for the MCRC64 module on this device. For Further information, see the Memory Cyclic Redundancy Check (MCRC64) section of the Peripherals chapter

4.13.3.1 MCRC64 Unsupported Features

The following features are not supported on this family of devices:

- Data Trace Mode (Automatic PSA on CPU Instruction and Data TCM busses) - Wrapper only supports VBUSM Signature Analysis. ITCM, DTCM designed for Cortex R5F
- DMA is not supported by the MCU instances

4.13.3.2 Module Allocations

Table 4-170. MCRC64 Modules Allocation within Device Domains

4.15 Display Subsystem (DSS)

This section contains the integration details for the DSS module on this device. For Further information, see the Display Subsystem (DSS) section of the Peripherals chapter

4.15.1 DSS_UL Unsupported Features

The following features are not supported on this family of devices:

- Video output from Port 1 (dpi_0 interface)
- Fragmented frame buffers
- OLDITX does not support independent displays on each link. Links may be combined to support a single 2K display, or the second link can be used to mirror the first link.
- Video output > 1920x1080 @ 60Hz
- Write-back pipeline for memory-to-memory composition
- 2-D Tiled buffer access
- On-the-fly rotation
- Compressed data format

4.16 Spinlock

This section contains the integration details for the Spinlock module on this device. For Further information, see the Spinlock section of the Peripherals chapter

4.16.1 SPINLOCK Unsupported Features

The following features are not supported on this family of devices:

- ARM Architectural Spinlock Instructions (LDREX,STREX)
- Any use model other than binary mutex (ex. counting semaphore, lockless programming) - Spinlock MMR is a single binary 0,1 implemented by a state machine
- 64 bit accesses - Spinlock MMRs are aligned on 32-bit boundaries meaning a 64 bit access affects the state of 2 spinlocks

4.16.2 Module Allocations

5.1 Initialization Overview

Figure 5-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip(s)
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software (SBL)
- **Initial software:** Software that loads, prepares, and passes control to application software or to the high-level operating system (HLOS)
- **High-Level Operating System** or bare-metal application which runs on main processor(s)

Figure 5-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

5.1.1 ROM Code Overview

ROM bootloader (or ROM Code) is a software that resides in a on-chip read-only memory (ROM) to assist the customer in transferring and executing their application code. The device has two ROM codes operating in tandem – the Public ROM code, and the M4 ROM code.

In order to accommodate various system scenarios, the ROM Code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host via the selected interface. Either the host writes the application code directly into internal memory or the ROM Code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

1. Hardware initialization phase
2. Boot process.

During initialization, the ROM Code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements.

During the boot process the boot image can be loaded into device memory and executed, or executed in place, depending on the boot peripheral. M4 will perform code verification and allow, or forbid, the image execution.

Main configuration source for boot after power-up are the BOOTMODE pins sampled automatically after reset release and stored in device status registers. At ROM Code startup, these pin values are read from the registers to create the boot peripheral list and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

5.1.2 Bootloader Modes

Table 5-1 shows the boot modes supported by ROM code.

Copyright © 2024 Texas Instruments Incorporated

Table 5-1. ROM Code Boot Modes

Boot Mode	Boot Media/Host	SoC Peripheral	Can be a Backup Mode?(1)	Notes
No-boot/Dev-boot	No media or host	None	N	No boot or development boot – debug modes
OSPI	OSPI flash	FSS0_OSPI0	N	On OSPI port
QSPI	QSPI flash	FSS0_OSPI0	N	On OSPI port
SPI	SPI flash	FSS0_OSPI0	Y	On OSPI port
Ethernet	External host	CPSW0	Y	In BOOTP mode. RGMII or RMII PHY
I2C	I^2C EEPROM	I2C0	Y	I2C target boot is not supported
UART	External host	UART0	Y	XMODEM protocol
MMCSD	eMMC flash or SD card	MMCSD0 (8bit) or MMCSD1 (4bit)	Y	Boot from User Data Area (UDA) in raw or file system mode
eMMC	eMMC flash	MMCSD0 (8bit)	N	Boot from boot partition
USB - target	USB boot from external host	USB0	Y	USB device mode boot using DFU (device firmware upgrade), Boot is running on USB2.0 speeds.
USB - host	USB mass storage	USB0	Y	USB2.0 host mode, boot from FAT32 filesystem
Serial Flash	Serial Flash	FSS0_OSPI0	N	On OSPI port
xSPI	xSPI flash	FSS0_OSPI0	N	On OSPI port
GPMC	NOR flash, NAND flash	GPMC0	N	CSn0 connected, 8 bit NAND flash only, 16-bit non-mux NOR flash only

(1) The peripheral can be selected also as a backup boot mode. A backup mode is tried if primary boot mode fails.

Note

Because different devices support different sets of peripherals, see the *device-specific Datasheet* to obtain the list of peripherals supported in your device.

5.1.3 Terminology

- **Boot Mode Pins:** Boot mode pins provide vital information to ROM code for boot. These pins must be properly set up before power ramp.
- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase.
- **Boot Header:** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings.
- **Downloaded software:** Initial software downloaded into on-chip RAM by the ROM code during the peripheral booting phase.
- **eFuse:** A one-time programmable memory location usually set at the factory.
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **GP device:** General-purpose device (SoC) or a non-secure device.
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software. This can be the SBL (secondary bootloader) responsible for loading an OS.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory.
- **Controller CPU:** The Arm® Cortex® CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.

Copyright © 2024 Texas Instruments Incorporated

- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory.
- **ROM Code:** or ROM bootloader (RBL), the on-chip software in device ROM that executes first and implements booting.
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the device ROM code.
- **Booting Parameter Table:** A logical structure stored in the on-chip RAM memory and contains information for the boot, such as the boot file name or an address to boot from.

5.2 Boot Process

5.2.1 Public ROM Code Architecture

The Public ROM code has the following components (see also Public ROM Code Architecture):

- Main
- Buffer manager
- X.509
- Log and Trace
- System
- Protocol
- Driver

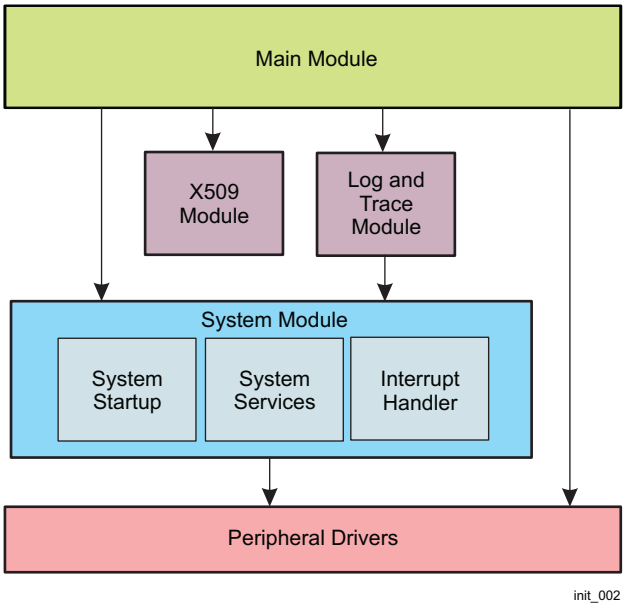

Figure 5-2. Public ROM Code Architecture

5.2.1.1 Main Module

The Main module contains the top level execution loop. This loop repeats until a boot image has been received or directed to sleep by the M4. The main loop has three different execution sub-paths based on the boot peripheral.

- **Image Path** This path is used by the OSPI, QSPI, SPI, and xSPI boot modes. In these cases the image data can be directly read by both the R5 and the M4 in place.
- **Block Path** This path is used by the I2C, USB-DFU, UART, eMMC, Ethernet, eMMC/SD cards in raw mode. In this mode data is received from the peripheral in blocks. Blocks are accumulated in the boot buffer until a full X.509 certificate header has been received, at which point this full certificate and any subsequent blocks are passed to the M4 as they arrive.
- **Filesystem Path** This path is used by the USB host (MSC) mode and eMMC/SD cards in filesystem mode. This mode executes exactly like in the block path, except that the boot image location is defined by a filesystem.

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images. In some cases, detection of an invalid image is done after the initial data buffer has been sent to the M4. In that case the R5 must inform the M4 that the image was in fact invalid and it will be looking for the next image and try again.

Copyright © 2024 Texas Instruments Incorporated

5.2.1.2 X509 Module

The X509 module parses the boot header. The boot header is an X.509 certificate as defined in RFC5280. Extensions specific to boot are described in Section 5.7.2, *X.509 Certificate*.

This module also includes an OID decoder as well as defines OID values as C #define constants for any values that can be used during boot.

5.2.1.3 Buffer Manager Module

The buffer manager module is used to allocate buffers to hold boot data. The R5 code allocates a buffer when it is ready to read a block of data from the boot peripheral. Once the data is read the buffer ownership is passed to the M4. When the M4 has completed processing the data in the buffer ownership is returned to the R5, which then frees the buffer.

5.2.1.4 Log and Trace Module

The Log and Trace modules are not integral to the boot process. Instead, they provide ability to record operation of the ROM code and track unexpected occurrences.

Log and trace function is currently TI internal.

5.2.1.5 System Module

The system module provides services to other modules. These services are not directly related to boot drivers. The system module is the only module that operates in the supervisor mode of the R5 (a few services will run in user). The system module supports the following functions:

- Interrupt enable, disable, and service
- IPC
- Power
- Pinmux
- Clock
- Task switch

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images.

5.2.1.6 Protocol Module

The protocol modules provide implementation of high-level data transfer protocols. The BOOTP/TFTP and XMODEM protocols reside in this layer. These modules provide services as defined in well-known standards.

5.2.1.7 Driver Module

The driver module implements the low level peripheral drivers.

5.2.2 M4 ROM Description

In a general-purpose (GP) device, M4 ROM performs the following functions:

- Device management
- Configures the boot vectors (in BOOT_CFG) and controls reset release of R5 core. That is, M4 is the boot controller of R5 core.
- IPC configuration via Main DMSS rings and Secure Proxy
- PLL configuration (R5 and SA2UL)
- X509 certificate parsing
- SA2UL configuration to SHA512 for image integrity checks
- M4 firmware loading

5.2.3 Boot Process Flow

The R5 boot process flow is shown in Figure 5-3.

Copyright © 2024 Texas Instruments Incorporated

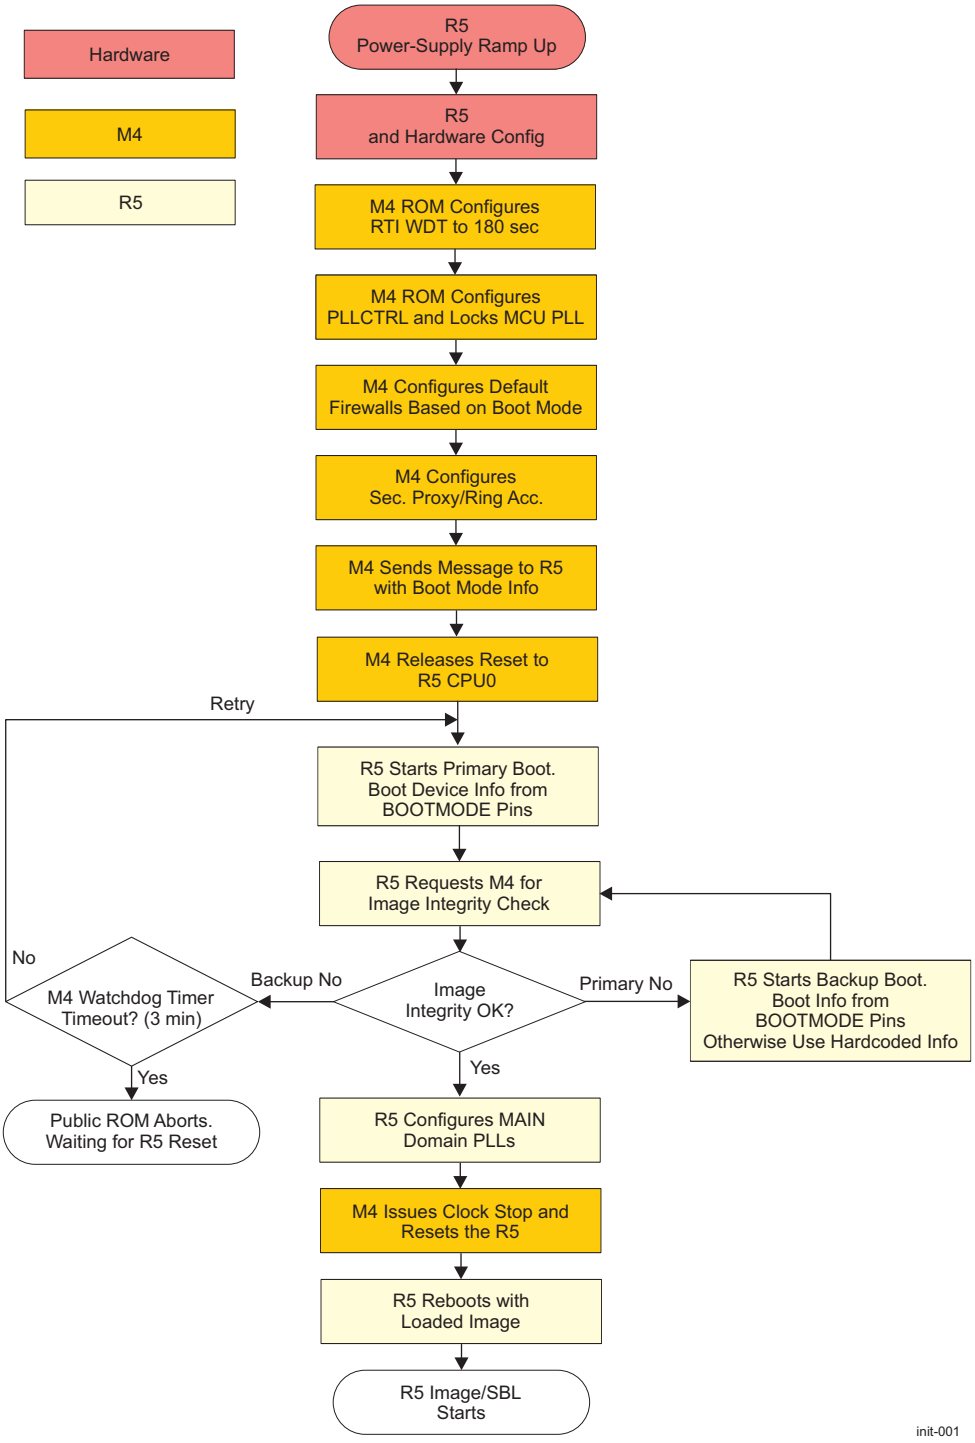

Figure 5-3. Boot Process

The values of BOOTMODE[15:0] pins are latched into the Device Status register CTRLMMR_MAIN_DEVSTAT[15:0] by hardware as the device comes out of global cold reset, sampled after MCU_PORz deassertion. For more information how to set BOOTMODE pins, see Section 5.3, *Boot Mode Pins*.

The M4 is the boot controller for the Public ROM. M4 performs the necessary configurations and releases R5's reset for CPU0.

Copyright © 2024 Texas Instruments Incorporated

The R5 checks the boot mode pins and then configures the apropriate peripheral interface to get access to a boot image. A cursory check of the image is made, and the image is passed to M4. M4 ROM then will perform code verification and route the boot image to the on-chip RAM. Once the image has been received, R5 enters a clean state and idles. M4 ROM code will assert reset to the R5, redirect the boot vector to the newly loaded image, and release the reset. This restarts the R5 with the Public ROM code fully disconnected.

The Public ROM code executes after a cold or warm reset.

Note

M4 ROM sets up a 3-minute watchdog timer (RTI0) timeout. During this time, the R5 boot needs to get completed, otherwise a WDT reset will occur. Once the R5 image is loaded (SBL/SPL), M4 ROM will restart the watchdog timer for additional 3 minutes upon entering the R5 SBL. The customer-provided R5 image needs to load and install the TI-provided SYSFW image into the M4, which will manage the watchdog timer during run time.

Note

The following system conditions must be met at POR to perform device boot:

- USB cable plug must be inserted
- Ethernet PHY is powered up and out of reset
- The SD card cage must be powered before entering the SD card boot mode. A SD/MMC card with pre-loaded image must be inserted
- Memory devices must be up and ready (power ramped up and reset completed) at device startup:
  - eMMC
  - xSPI/OSPI/QSPI/SPI and Serial flash
  - I2C EEPROM
  - NOR/NAND flash

Failing to meet these requirements may result in boot fail and performing a backup boot (if available for that mode).

Figure 5-4 describes the external bootloader (SBL) typical tasks.

Copyright © 2024 Texas Instruments Incorporated

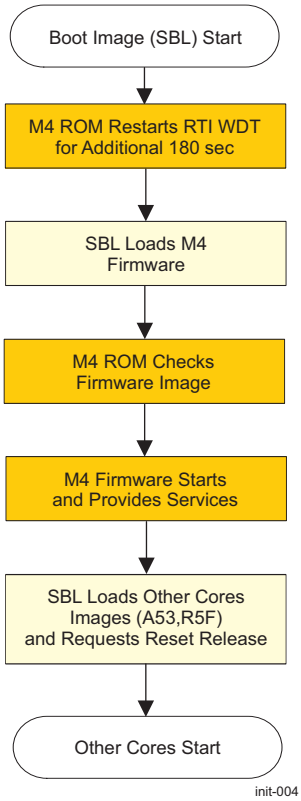

Figure 5-4. External Bootloader Tasks

Upon R5 reset and SBL execution start, M4 ROM restarts the RTI watchdog timer for additional 180 seconds of timeout. During that time, SBL must load the M4 firmware provided by TI otherwise an R5 reset will occur as a preventive measure against software misbehavior.

One of the SBL's main tasks is to load the M4 firmware. Only after this task is performed, SBL can load the other processors' image and request a reset release from M4 firmware for those cores.

5.3 Boot Mode Pins

Boot Mode pins provide means to select the boot mode and options before the device is powered up. After every POR, they are the main source to populate the Boot Parameter Tables. See Section 5.6, *Boot Parameter Tables* for table list and description.

Boot mode pins can be divided into the following categories:

- **BOOTMODE[02:00]** – Denote system clock frequency (MCU_OSC0_XI/XO) to ROM code for PLL configuration.
- **BOOTMODE[06:03]** – Select the requested boot (primary) mode after POR, that is, the peripheral/memory to boot from.
- **BOOTMODE[09:07]** – These pins provide optional configurations for primary boot and are used in conjunction with the boot mode selected.
- **BOOTMODE[12:10]** – Select the backup boot mode, that is, the peripheral/memory to boot from, if primary boot device failed.
- **BOOTMODE[13]** – This pin provides optional configurations for the backup boot devices.
- **BOOTMODE[15:14]** – Reserved pins.

Note

It is user's responsibility to set the boot mode pins (via pullups or pulldowns, and jumpers/switches) depending on the desired boot scenario.

Copyright © 2024 Texas Instruments Incorporated

5.3.1 BOOTMODE Pin Mapping

The ROM execution is directed through the main boot mode pins. This provides more flexibility and more booting peripherals to boot from. The Main domain must be powered and functional.

Main boot mode pins are shown in Table 5-2.

Any Bootmode pins marked as Reserved or not used must be tied high or low with pull resistors. They should not be left floating.

Table 5-2. BOOTMODE Pin Mapping

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Reserved	Backup Boot Mode Config	Backup Boot Mode			Primary Boot Mode Config			Primary Boot Mode				PLL Config		

Table 5-3 describes the BOOTMODE pins that need to be set according to the system clock provided to the device.

The ROM Code will configure any PLLs required during the boot process.

Note

Reference clock selections may be limited by the device. Please consult the device specific datasheet to determine which system clock frequencies are valid.

Table 5-3. PLL Reference Clock Selection

PLL Config Pins			Ref Clock (MHz)
B2	B1	B0	
0	0	0	19.2
0	0	1	20
0	1	0	24
0	1	1	25
1	0	0	26
1	0	1	27(1)
1	1	0	Reserved
1	1	1	Reserved

(1) USB DFU boot mode is not supported with the reference clock of 27 MHz.

5.3.1.1 Primary Boot Mode Selection and Configuration

The primary boot mode is the first mode attempted after reset. Table 5-4 lists all possible primary boot modes. All pins marked as reserved can be either 0 or 1. All boot mode signals must be pulled low or high through a pull resistor on the board, they must not be left floating

Note

All BOOTMODE[15:00] signals must be pulled high through a resistor to VDDSHV3, or pulled low to ground, including Reserved signals. Reserved BOOTMODE signals must not be left floating.

Table 5-4. Primary Boot Mode Selection

Primary Boot Mode Config							Primary Boot Mode
B9	B8	B7	B6	B5	B4	B3	
Reserved	Read Mode 2	Read Mode 1	0	0	0	0	Serial NAND
Reserved	Iclk	Csel	0	0	0	1	OSPI
Reserved	Iclk	Csel	0	0	1	0	QSPI

Reserved	Reserved	Reserved	0	1	1	1	UART
Port	Reserved	Fs/raw	1	0	0	0	MMCSD Boot (SD Card Boot or eMMC Boot using UDA)
Reserved	Reserved	Reserved	1	0	0	1	eMMC Boot
Core Volt	Mode	Lane Swap	1	0	1	0	USB
Reserved	Reserved	Reserved	1	0	1	1	GPMC NAND
Reserved	Reserved	Reserved	1	1	0	0	GPMC NOR
Reserved	Reserved	Reserved	1	1	0	1	Reserved
SFPD	Read Cmd	Mode	1	1	1	0	xSPI
Reserved	ARM/Thumb	No/Dev	1	1	1	1	No-boot/Dev boot

5.3.1.2 Backup Boot Mode Selection and Configuration

The backup boot mode is selected via pins within the main BOOTMODE map. Table 5-5 lists all possible backup boot modes.

Table 5-5. Backup Mode Selection

Backup Boot Config	Backup Boot Mode Selection			Backup Boot Mode Selected
B13	B12	B11	B10	
Reserved	0	0	0	None
Mode	0	0	1	USB
Reserved	0	1	0	Reserved
Reserved	0	1	1	UART
IF	1	0	0	Ethernet
Port	1	0	1	MMCSD Boot (SD Card Boot or eMMC Boot)
Reserved	1	1	0	SPI
Reserved	1	1	1	I2C

5.4 Boot Modes

Copyright © 2024 Texas Instruments Incorporated

5.4.1 OSPI\xSPI\QSPI\SPI Boot

The following apply to all or multiple boot modes that are SPI related.

- Octal SPI flash memories support various protocols, however, the OSPI boot mode of the device will only support a specific protocol defined in OSPI Bootloader Operation. If the flash memory is complaint with JEDEC xSPI standards JESD251 and JESD216D, then xSPI boot mode is additionally supported. Please refer to xSPI boot mode description for further details.
- Command protocols follow the JEDEC spec definition and indicate the number of active pins used for the instruction, address, and data, and also the data rate used for each (S = Single Data Rate, D= Double Data Rate). For example, 1S-1S-8S describes a protocol which uses 1 signal (D0) for command in SDR mode, 1 signal (D0) for address in SDR mode, and 8 signals (D7:D0) for data in SDR mode
- When using a OSPI\xSPI\QSPI\SPI flash device greater than 128Mb, a flash device package with a RESET signal (NOR type memories only) must be used. The reason is that the ROM only uses 3 byte addressing mode (address is 24bits). To address the full memory address range, software will typically switch to 4-byte addressing mode. If a reset to the processor occurs (eg, due to a warm reset), the ROM will execute expecting 3-byte addressing mode, but the flash will have been left in 4-byte addressing mode. In order for the flash device to return to 3-byte addressing mode, it must be reset using this signal. This typically can be achieved by using the RESET signal on the flash memory device. The ROM does not issue a software reset command.
- When booting from any of the SPI boot modes, BOOTMODE pin settings will depend on operation during normal operation
  - To support high speed OSPI with the DQS signal during normal operation, set BOOTMODE8=1 to use internal iclk during boot and ensure signal LBCLKO is a no connect (ie, absolutely no trace can be connected to LBCLKO). The ROM boot will operate OSPI at low speed (50MHz), and during normal operation, the OSPI interface can use the DQS signal to operate the interface at high speeds.
  - To support high speed OSPI or QSPI without DQS signal (ie, using the LBCLKO signal to support loopback clock), then set BOOTMODE8=0 to use external clock during boot. In this case, ROM boot and normal operation will use the externally looped back clock signal LBCLKO. Board designers should refer to the device specific datasheet to undertstand board routing guidelines for the LBCLKO signal.
  - To support only low speed OSPI\xSPI\QSPI\SPI operation (ie, <=50MHz OSPI clock), set BOOTMODE8=1 to use internal iclk, and ensure signal LBCLKO is a no connect (ie, absolutely no trace can be connected to LBCLKO). Operation for both ROM boot and normal operating mode will clock the interface at low speed and use the internally pad looped back clock. The DQS and LBCLKO signals will not be used during boot or normal operation

5.4.1.1 OSPI Boot

Table 5-6 shows configuration pins assignment to functions when boot mode is the Octal SPI using the OSPI module. The BOOTMODE pin corresponding to the Iclk field determines the setting for LOOPCLK_SEL bit field in CTRLMMR_OSPI0_CLKSEL register

Table 5-6. OSPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
8	Iclk	0	Iclock source external
		1	Iclock source internal (pad loopback)
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-7 summarizes the OSPI pin configuration done by ROM code for OSPI boot device.

Table 5-7. OSPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_LBCLKO	OSPI0_LBCLKO	Disable	NA	0	Enable	0	PADCONFIG1
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.1.1 OSPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to OSPI boot mode

The OSPI boot mode supports 1S-1S-8S mode only. The ROM will issue a Read Command (0x8B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The flash device should then respond with 8-bit data. The frequency of operation during the read portion is 50 MHz.

5.4.1.1.1.1 OSPI Initialization Process

In the OSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the OSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See Section 5.4.1.1, *OSPI Boot Device Configuration* for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI Boot Parameter Table*.

Copyright © 2024 Texas Instruments Incorporated

5.4.1.1.1.2 OSPI Loading Process

OSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2024 Texas Instruments Incorporated

5.4.1.2 xSPI Boot

Table 5-8 shows configuration pins assignment to functions when boot mode is xSPI using the OSPI module.

Table 5-8. xSPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	SFDP	0	SFDP disabled
		1	SFDP enabled
8	Read cmd	0	0x0B Read Command
		1	0xEE Read Command
7	Mode	0	1S-1S-1S mode @ 50MHz
		1	8D-8D-8D mode @ 25MHz

Table 5-9 summarizes the OSPI pin configuration done by ROM code for xSPI boot device on port 0.

Table 5-9. xSPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_LBCLKO	OSPI0_LBCLKO	Disable	NA	0	Enable	0	PADCONFIG1
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.2.1 xSPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to xSPI boot mode

The xSPI protocol defines 1S-1S-1S mode for general backwards compatibility, and 8D-8D-8D for maximum throughput.

For 1S-1S-1S mode of operation, the ROM will issue a Fast Read Output command (0x0B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The frequency of operation is 50 MHz.

For 8D-8D-8D mode of operation, the ROM will issue a Fast Read command (0x0B or 0xEE, depending on BOOTMODE signal), followed by a 32 bit (4 byte) address (the starting address is all zeros). The frequency of operation is 25 MHz.

When SFDP is enabled using a BOOTMODE signal, the ROM starts operation in 1S-1S-1S mode reads SFDP header from flash memory to get 8D-8D-8D switching sequence, Read Command, CMD Extension and Byte Order. SFDP parsing of ROM is described below and on successful parsing ROM will issue 8D-8D-8D command

Copyright © 2024 Texas Instruments Incorporated

switching sequence and then will read the boot image in 8D-8D-8D mode with read command specified in SFDP header

Copyright © 2024 Texas Instruments Incorporated

5.4.1.3 QSPI Boot

Table 5-10 shows configuration pins assignment to functions when boot mode is QSPI using the OSPI module. The BOOTMODE pin corresponding to the Iclk field determines the setting for LOOPCLK_SEL bit field in CTRLMMR_OSPI0_CLKSEL register

Table 5-10. QSPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
8	Iclk	0	Iclock source external
		1	Iclock source internal (pad loopback)
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-11 summarizes the OSPI pin configuration done by ROM code for QSPI boot device on port 0.

Table 5-11. QSPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Strength Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_LBCLKO	OSPI0_LBCLKO	Disable	NA	0	Enable	0	PADCONFIG1
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.3.1 QSPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to QSPI boot mode

The QSPI boot mode supports the 1S-1S-4S mode only. The ROM will issue a Fast Read Quad Output command (0x6B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The flash device should then respond with 4-bit data. The frequency of operation during the quad read portion is 50 MHz.

5.4.1.3.1.1 QSPI Initialization Process

In the QSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the QSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See Section 5.4.1.3, *QSPI Boot Device Configuration* for OSPI port settings.

A detailed summary of the QSPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *QSPI Boot Parameter Table*.

5.4.1.3.1.2 QSPI Loading Process

QSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2024 Texas Instruments Incorporated

5.4.1.4 SPI Boot

Table 5-12 shows configuration pins assignment to functions when boot mode is SPI using the OSPI module.

Table 5-12. SPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
8	Mode	0	SPI Mode 0
		1	SPI Mode 3
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-13 summarizes the OSPI pin configuration done by ROM code for SPI boot device on port 0.

Table 5-13. SPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_LBCLKO	OSPI0_LBCLKO	Disable	NA	0	Enable	0	PADCONFIG1
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.4.1 SPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to SPI boot mode

The SPI boot mode supports the 1S-1S-1S mode only. The Read Command is 8-bits (0x03) followed by a 24 bit (3 byte) address. There are no dummy cycles issued after the read command. The frequency of operation supported is 6.250 MHz. OSPI0_D0 will have data transfers **FROM** the processor **TO** the flash device, and OSPI0_D1 will have data transfers **TO** the processor **FROM** the flash device

5.4.1.4.1.1 SPI Initialization Process

In the SPI boot mode, the ROM Code initializes the OSPI peripheral to SPI mode and the image is read from the flash memory connected to the corresponding OSPI port and chip-select. A detailed summary of the SPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI/QSPI/SPI Boot Parameter Table*. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM.

5.4.1.4.1.2 SPI Loading Process

SPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2024 Texas Instruments Incorporated

5.4.2 I2C Boot

Table 5-14 shows configuration pins assignment to functions when boot mode is the I2C mode.

Table 5-14. I2C Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	Bus reset	0	Hung bus reset attempt after 1 ms
		1	No hung bus reset attempted
7	Address	0	EEPROM's address is 0x50
		1	EEPROM's address is 0x51

The I^2C bus is considered inactive if the data line is low and clock remains high for the specified timeout time. Recovery consists of driving the clock a stop condition is detected. A stop condition is a transition on the data line from 0 to 1 while the clock line is high. If the clock line is stuck low there is no way to take control of the bus.

Table 5-15 summarizes the I2C pin configuration done by ROM code for I^2C boot device.

Table 5-15. I2C Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
I2C0_SCL	I2C0_SCL	Disable	NA	0	Enable	0	PADCONFIG120
I2C0_SDA	I2C0_SDA	Disable	NA	0	Enable	0	PADCONFIG121

5.4.2.1 I2C Bootloader Operation

5.4.2.1.1 I2C Initialization Process

In the I2C boot mode, the ROM Code configures the Main Domain I2C0 in controller mode.

The boot controller drives the I^2C target device where the image is stored. The image is copied to internal RAM, and is executed from there. If the image is not recognized, the ROM will attempt to read the image at offset 0x8000. This is the only redundant image supported by the ROM.

A detailed summary of the I^2C boot parameter table and the BOOTMODE pins definitions are listed in Section 5.6.5, *I2C Boot Parameter Table* and Section 5.4.2, *I2C Boot Device Configuration*.

5.4.2.1.1.1 Block Size

ROM code will read 0x800 bytes before processing the data. The last block must be padded to the next 0x800 byte boundary and it must be padded with zeros.

5.4.2.1.1.2 Addressing

The boot code does not support byte address to bus address wrapping. So the maximum image size that can be access is 64 kbytes. For example, if the read address is 0xFF00, the read size is 0x200 and the I^2C bus address is 0x50, then 0x100 bytes will be read from 0xFF00 at bus address 0x50, followed by 0x100 bytes from 0x0000 at bus address 0x50. The bus address does not increment when the address rolls over.

5.4.2.1.2 I2C Loading Process

5.4.2.1.2.1 Loading a Boot Image From EEPROM

In this mode, the Main Domain I2C0 peripheral is configured as I^2C controller.

ROM Code will start reading from the I^2C EEPROM at the specified I^2C bus address. This read will be done beginning at the specified base address offset. Data will be read in 2-KB chunks. The data will be stored at the address specified in the boot header. It will continue reading image data until a complete image has been read. When the complete image has been read, the ROM Code will branch to the start address of the image.

Copyright © 2024 Texas Instruments Incorporated

5.4.3 SD Card Boot

Table 5-16 shows configuration pins assignment to functions when boot mode is the SD card boot mode.

Table 5-16. SD Card Boot Configuration Fields

SD Card Boot Configuration Fields			
BOOTMODE Pins	**Field**	**Value**	**Description**
9 (13[1])	Port	0	Reserved
		1	MMC Port 1 (4 bit width). This bit must be set to 1
7	FS/Raw	0	Filesystem mode
		1	Raw Mode

(1) When MMCSD is the backup mode.

Table 5-17 summarizes the MMCSD pin configuration done by ROM code for SD Card boot on port1 (MMCSD1). SD Card boot on Port 0 (MMCSD0) is not supported.

Table 5-17. SD Card (MMCSD1) Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
MMC1_DAT3	MMC1_DAT3	Disable	NA	0	Enable	0	PADCONFIG137
MMC1_DAT2	MMC1_DAT2	Disable	NA	0	Enable	0	PADCONFIG138
MMC1_DAT1	MMC1_DAT1	Disable	NA	0	Enable	0	PADCONFIG139
MMC1_DAT0	MMC1_DAT0	Disable	NA	0	Enable	0	PADCONFIG140
MMC1_CLK	MMC1_CLK	Disable	NA	0	Enable	0	PADCONFIG141
MMC1_CLKLB	MMC1_CLKLB	Disable	NA	0	Enable	0	PADCONFIG142
MMC1_CMD	MMC1_CMD	Disable	NA	0	Enable	0	PADCONFIG143
MMC1_SDCD	MMC1_SDCD	Disable	NA	0	Enable	0	PADCONFIG144

Note

MMC1_CLKLB signal is not pinned out on the device. The pinmux configuration enables the input buffer of the internal loopback clock.

Note

MMC1_SDWP is not configured by ROM since the ROM never writes to the SD card.

5.4.3.1 SD Card Bootloader Operation

SD Card boot is only available on Port 1 of the MMCSD controller (MMCSD1). The IOs on this port support both 1.8V and 3.3V operation, as well as dynamic voltage change. Thus, this port can support initial operation at 3.3V and remain at this voltage for legacy SD Cards, or support initial operation at 3.3V and change to 1.8V after ROM boot for UHS-I SD Cards.

The ROM will boot from SD cards using one of these methods:

- User Data Area (UDA) in raw mode
- User Data Area (UDA) in filesystem mode

The ROM is capable of booting from any size SD card because the MMCSD controller is responsible for addressing. Only single data rate with backward compatible interface timing is supported.

The MMCSD module depends on proper voltage level on the SD card detect signal (SDCD). If SDCD=1, the ROM will assume the card is not present and will fail the boot mode.The SDCD must be 0 for the ROM to

Copyright © 2024 Texas Instruments Incorporated

continue to attempt to boot. Card detect using DAT3 is not supported. If the card is detected, the initial discovery phase is performed:

1. Send CMD 0. (GO IDLE, both for MMC and SD)
2. Send CMD 55. If the card responds then the card type is assumed to be SD. On timeout the code sends CMD 1. If there is a response then the card type is MMC.

The ROM Code will start reading from the MMCSD memory boot sector, or filesystem, as specified by the BOOTMODE pins. Only FAT32 and FAT16 formats are supported in filesystem mode. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. In RAW mode only, the ROM supports a redundant image at offset 0x400000 in case the initial image fails to be recognized. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

When SD Card boot is used as a backup boot option, only User Data Area (UDA) in filesystem mode is supported. Raw mode is not supported. Additionally, boot will only occur in 1-bit mode during backup booting.

Copyright © 2024 Texas Instruments Incorporated

5.4.4 eMMC Boot

Table 5-18 shows configuration pins assignment to functions when boot mode is the eMMC Boot using a UDA boot mode (BOOTMODE[6:3]=1000b). Note that eMMC Boot using alternate eMMC Boot (BOOTMODE[6:3]=1001b) does not have any extra bootmode configuration fields. See Section 5.4.4.1 for more information.

Table 5-18. eMMC Boot Configuration Fields (UDA mode)

eMMC Boot Configuration Fields			
BOOTMODE Pins	**Field**	**Value**	**Description**
9 (13[1])	Port	0	MMCSD Port 0 (8 bit width). This bit must be set to 0
		1	Reserved
7	FS/Raw	0	Filesystem mode
		1	Raw Mode

(1) When MMCSD Boot is the backup mode.

Table 5-19 summarizes the MMCSD pin configuration done by ROM code for eMMC boot on port0 (MMCSD0). eMMC boot on Port 1 (MMCSD1) is not supported.

Table 5-19. eMMC (MMCSD Port 0) Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
MMC0_DAT7	MMC0_DAT7	Enable	Up	0	Enable	0	PADCONFIG126
MMC0_DAT6	MMC0_DAT6	Enable	Up	0	Enable	0	PADCONFIG127
MMC0_DAT5	MMC0_DAT5	Enable	Up	0	Enable	0	PADCONFIG128
MMC0_DAT4	MMC0_DAT4	Enable	Up	0	Enable	0	PADCONFIG129
MMC0_DAT3	MMC0_DAT3	Enable	Up	0	Enable	0	PADCONFIG130
MMC0_DAT2	MMC0_DAT2	Enable	Up	0	Enable	0	PADCONFIG131
MMC0_DAT1	MMC0_DAT1	Enable	Up	0	Enable	0	PADCONFIG132
MMC0_DAT0	MMC0_DAT0	Disable	NA	0	Enable	0	PADCONFIG133
MMC0_CLK	MMC0_CLK	Disable	NA	0	Enable	0	PADCONFIG134
MMC0_CLKLB	MMC0_CLKLB	Disable	NA	0	Enable	0	PADCONFIG135
MMC0_CMD	MMC0_CMD	Disable	NA	0	Enable	0	PADCONFIG136

Note

MMC0_CLKLB signal is not pinned out on the device. The pinmux configuration enables the input buffer of the internal loopback clock.

5.4.4.1 eMMC Bootloader Operation

Booting from an eMMC device is only available on Port 0 of the MMCSD controller (MMCSD0). Booting from an eMMC device is not available on Port1 (MMCSD1) or MMCSD2. The IOs associated with MMCSD0 port support both 1.8V and 3.3V eMMC operation

The ROM will boot from eMMC devices using one of these methods:

- User Data Area (UDA) in raw mode
- User Data Area (UDA) in filesystem mode
- eMMC bootmode (alternate)

To boot from UDA in either raw or filesystem mode, choose bootmode "MMCSD Boot" (see Table 5-4).

A special alternate boot mode is available with eMMC devices which allows the ROM to boot from an image that is in a separate boot partition in the eMMC. To boot from this mode, choose "eMMC Boot" (see Table 5-4).

Copyright © 2024 Texas Instruments Incorporated

The ROM Code will start reading from the memory boot sector, filesystem, or boot partition as specified by the BOOTMODE pins. Only FAT32 and FAT16 formats are supported in filesystem mode. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. In RAW mode only, the ROM supports a redundant image at offset 0x400000 in case the initial image fails to be recognized. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

When eMMC boot is used as a backup boot option, only User Data Area (UDA) in filesystem mode is supported. Raw mode is not supported. Additionally, boot will only occur in 1-bit mode during backup booting.

5.4.5 Ethernet Boot

Table 5-20 shows configuration pins assignment to functions when boot mode is the Ethernet RGMII mode.

Table 5-20. Ethernet RGMII Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	Clkout	0	25 MHz clock not generated on CLKOUT0
		1	25 MHz clock generated on CLKOUT0
8	Delay	0	Must be set to 0 for RGMII with internal Tx delay
		1	Reserved
7	Link info	0	MDIO PHY scan used for link parameters.
		1	Link parameters programmed by the ROM

Table 5-21 shows configuration pins assignment to functions when boot mode is the Ethernet RMII mode.

Table 5-21. Ethernet RMII Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	Clkout	0	50 MHz clock not generated on CLKOUT0
		1	50 MHz clock generated on CLKOUT0
8	Clk src	0	External clock source for RMII1_REF_CLK
		1	Internal clock source for RMII1_REF_CLK
7	RMII	0	This bit must be set to 0
		1	Reserved

Table 5-22. Ethernet RMII Clocking

BOOTMODE Pin 9 (Clk out)	BOOTMODE Pin 8 (Clk src)	Description
0	0	50MHz external source to RMII_REF_CLK and to external Ethernet PHY input clock (CLKOUT0 is unused) These are the recommended settings
0	1	Not a valid configuration
1	0	CLKOUT0 is configured to 50MHz and connect to both RMII1_REF_CLK and to external Ethernet PHY input clock
1	1	Not a valid configuration

Table 5-23 shows configuration pins assignment to functions when the backup boot mode Ethernet. The Interface configuration field chooses which interface will be used (RGMII or RMII)

Table 5-23. Ethernet Backup Boot Configuration Field

BOOTMODE Pins	Field	Value	Description
13	Interface	0	RGMII with internal TX delay
		1	RMII with external clock source

Table 5-24 summarizes the RGMII pin configuration done by ROM code for Ethernet boot device on RGMII port.

Table 5-24. RGMII Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
RGMII1_TX_CTL	RGMII1_TX_CTL	Disable	NA	0	Disable	0	PADCONFIG75
RGMII1_TXC	RGMII1_TXC	Disable	NA	0	Disable	0	PADCONFIG76
RGMII1_TD0	RGMII1_TD0	Disable	NA	0	Disable	0	PADCONFIG77
RGMII1_TD1	RGMII1_TD1	Disable	NA	0	Disable	0	PADCONFIG78
RGMII1_TD2	RGMII1_TD2	Disable	NA	0	Disable	0	PADCONFIG79
RGMII1_TD3	RGMII1_TD3	Disable	NA	0	Disable	0	PADCONFIG80

RGMII1_TD1	RMII1_TXD1	Disable	NA	0	Disable	1	PADCONFIG78
RGMII1_TX_CTL	RMII1_TX_EN	Disable	NA	0	Disable	1	PADCONFIG75
RGMII1_TXC	RMII1_CRS_DV	Disable	NA	0	Enable	1	PADCONFIG76
EXT_REFCLK1(1)	CLKOUT0	Disable	NA	0	Disable	5	PADCONFIG124
MDIO0_MDIO	MDIO0_MDIO	Disable	NA	0	Enable	0	PADCONFIG87
MDIO0_MDC	MDIO0_MDC	Disable	NA	0	Disable	0	PADCONFIG88

(1) Enabled when CLKOUT0 option is selected from boot pin selection.

5.4.5.1 Ethernet Bootloader Operation

5.4.5.1.1 Ethernet Initialization Process

When the device is set to boot through the Ethernet mode, the ROM Code configures the Ethernet module and the interface mode (RMII, RGMII) according the the BOOTMODE pin settings, see Section 5.4.5, *Ethernet Boot Device Configuration*. Also consult the boot parameter table for the Ethernet boot, see Section 5.6.7, *Ethernet Boot Parameter Table*.

When Link Info = 0, the link parameters are read using MDIO scan. This is the typical setting when using an external PHY. With these parameters, the ROM identifies the PHY and establishes link with the supported speed and duplex mode.

When Link Info = 1, no MDIO scan is performed, and the link parameters are programmed by the ROM based on the RGMII status register. This is the typical setting when configured as a MAC to MAC RGMII interface whereby RGMII pins of two devices can be connected diretly and establish link in force mode. The chosen configuration will be Gigabit, full duplex mode.

Note that booting from RGMII requires that an attached PHY be configured for RGMII-ID Mode immediately upon exiting reset. The ROM will not make this configuration change to the PHY.

The ROM will setup RGMII mode enabling internal delay mode.

Copyright © 2024 Texas Instruments Incorporated

5.4.5.1.2 Ethernet Loading Process

After device configuration, the bootloader performs a standard BOOTP/TFTP boot. The device sends a BOOTP request with its MAC address to a host TFTP server to be assigned an IP from a pool of addresses. The timeout for each BOOTP packet is 4 seconds, and the ROM will attempt 10 BOOTP retries, after which the boot mode will fail. If the connection is established, the device initiates a TFTP download and is able to receive image data encapsulated in Ethernet packets, see Section 5.4.5.1.2.1. There is a timeout of 1 second to receive a response for the READ request, and the ROM will retry the READ request 10 times, after which the boot mode will fail. If TFTP download is successful, data received is stripped of its network headers and the boot data is stored in internal RAM. When the transfer completes and the image is found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

5.4.5.1.2.1 Ethernet Boot Data Formats

Ethernet boot uses the BOOTP/TFTP protocol for downloads. Only IPv4 is supported.

5.4.5.1.2.1.1 Limitations

- Received packets cannot be IP fragmented (should not be a problem in most systems since the BOOTP/TFTP packets have fixed lengths of small size)
- Only DIX Ethernet headers are supported.
  - 802.3 with SNAP/LLC not supported
  - DIX Ethernet with VLAN not supported
  - 802.3 with VLAN and SNAP/LLC not supported

5.4.5.1.2.1.2 BOOTP Request

5.4.5.1.2.1.2.1 MAC Header (DIX)

- Destination MAC = value from parameter table (default is broadcast)
- Source MAC = value from parameter table (default is e-fuse value)
- Type = IPv4 (0x0800)

5.4.5.1.2.1.2.2 IPv4 Header

- Version = 4
- Header length = 0
- TOS = 0
- Len = computed during operation
- ID = 0x0001
- Flags + Fragment offset = 0
- TTL = 0x10
- Protocol = UDP (17)
- Header checksum = Computed during operation
- SRC IP = 0.0.0.0
- Dest IP = 255.255.255.255

5.4.5.1.2.1.2.3 UDP Header

- Source port = BOOTP client (68 decimal)
- Destination Port = BOOTP server (67 decimal)
- Length = computed during operation
- Checksum = computed during operation

5.4.5.1.2.1.2.4 BOOTP Payload

- Opcode = Request (1)
- HW Type = Ethernet (1)
- HW Addr Len = 6
- Hop Count = 0
- Transaction ID = 1
- Number of seconds = 0

Copyright © 2024 Texas Instruments Incorporated

- Client IP = 0.0.0.0
- Your IP = 0.0.0.0
- Server IP = 0.0.0.0
- Gateway IP = 0.0.0.0
- Client HW Address = Device MAC address (from parameter table)
- Server hostname = NULL
- Filename = NULL
- Option 60, Vendor ID string, from parameter table
- Option 61, Client ID string, from parameter table

5.4.5.1.2.1.2.5 TFTP

There are no ROM code specific TFTP configurations.

5.4.5.1.3 Ethernet Hand Over Process

Once the ROM Code receives the valid packet, it decodes it to get the image sections and loads them in the appropriate memory location. After the image is loaded and validated, the ROM Code starts the boot image execution.

Copyright © 2024 Texas Instruments Incorporated

5.4.6 USB Boot

Table 5-26 shows configuration pins assignment to functions when boot mode is the USB mode.

Table 5-26. USB Boot Configuration Fields

USB Configuration Fields for Primary Boot Mode			
BOOTMODE Pins	**Field**	**Value**	**Description**
9	CoreVoltage	0	0.85V core voltage
		1	0.75V core voltage
8 (13[(1)])	Mode	0	DFU (USB device firmware upgrade)
		1	Host (MSC boot)
7	Lane Swap	0	D+/D- lines are not swapped
		1	D+/D- lines are swapped

(1) When USB is the backup mode.

Table 5-27 summarizes the USB pin configuration done by ROM code for USB boot device on port 0.

Table 5-27. USB Port 0 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
USB0_DRVVBUS	USB0_DRVVBUS	Disable	NA	0	Disable	0	PADCONFIG149

Note

Note that other USB pins do not have pin mux options. USB_DRVVBUS is configured in DFU mode even though it is not used.

Note on USB backup boot:

- Lane Swap (D+/D- lines) are not allowed

Configurability (pins) of these options do not exist in the USB backup boot mode.

CAUTION

A USB Type-AB connector should not be connected to another host when the device is booting as a USB Host. This will prevent two USB power sources from being connected together.

5.4.6.1 USB Bootloader Operation

The USB boot mode is used to read the boot image from external USB host.

See Section 5.4.6, *USB Boot Device Configuration* and Section 5.6.10, *USB Boot Parameter Table* for the available configuration options.

More information about USB DFU protocol can be found at http://www.usb.org/sites/default/files/DFU_1.1.pdf.

In DFU mode, the ROM will attempt an enumeration for 60 seconds, after which the boot mode will fail. If a successful enumeration is achieved, the ROM Code will start reading from the external host as specified by the BOOTMODE pins. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

5.4.6.1.1 USB-Specific Attributes

5.4.6.1.1.1 DFU Device Mode

- Vendor ID = 0x451
- Product ID = 0x6165
- Device ID = 0

Copyright © 2024 Texas Instruments Incorporated

5.4.7 UART Boot

ROM Code always configures the UART port to 115200 kbaud, 8-n-1 mode, and the XMODEM protocol is used to transfer the boot data.

Table 5-28 summarizes the UART pin configuration done by ROM code for UART host on port 0.

Table 5-28. UART Port 0 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
UART0_TXD	UART0_TXD	Disable	NA	0	Disable	0	PADCONFIG115
UART0_RXD	UART0_RXD	Disable	NA	0	Enable	0	PADCONFIG114

5.4.7.1 UART Bootloader Operation

5.4.7.1.1 Initialization Process

In the UART boot mode, the selected UART module (port) is the only peripheral configured. The baud rate, data, parity, and stop bits are configured based on the information in the UART boot parameter table. The boot parameter table definitions and the boot configuration values that can be set are in Section 5.4.7, *UART Boot Device Configuration* and Section 5.6.4, *UART Boot Parameter Table*.

Once the ROM Code configures the UART, it sends the UART pings for few seconds, which can be seen in the host. The pings consist of an ASCII capital *C* character. The UART boot mode supports only the CRC mode of XMODEM and does not support CHECKSUM mode. Both 128 and 1024 byte block sizes are supported.

5.4.7.1.2 UART Loading Process

Before the ping from the device stops, load the boot image from the host using the XMODEM protocol.

5.4.7.1.2.1 UART XMODEM

The XMODEM protocol is used to transfer boot data. Only CRC mode is supported (not checksum), with both 128- and 1024-byte block sizes. The general, format of received frames is shown in Table 5-29 and Table 5-30.

Table 5-29. XMODEM 1024- and 128-byte Data Frames

STX	Block Num	Inv Block Num	1024 data bytes		CRC	CRC
SOH	Block Num	Inv Block Num	128 data bytes	CRC	CRC	

Table 5-30. XMODEM Data Frame Fields

Field	Value	Description
STX	0x02	The start character for 1024-byte CRC data blocks
SOH	0x01	The start character for 128-byte CRC data block
Block Num	0x01-0xFF – 0x00	The block number. The first block has value 1, and the block number wraps around 0xFF to 0
Inv Block Num	0xFE-0x00	The inverse block number (bit inverse of the block number)
CRC	Calculated	The 16-bit CRC generated from the polynomial 0x1021

The XMODEM protocol is implemented as a half-duplex protocol as shown in Table 5-31.

Table 5-31. Example of XMODEM Transfer protocol

Transmitter Sends		Receiver Sends
	←	Ping (‘C’)
Frame 1	→	
	←	ACK (or NACK)
Frame 2	→	
	←	ACK (or NACK)
EOT	→

5.4.8 GPMC NOR Boot

There are no configuration fields for this boot mode. GPMC NOR boot only supports 16-bit non-mux memory.

Table 5-32 summarizes the GPMC pin configuration done by ROM code for GPMC NOR boot.

Table 5-32. GPMC NOR Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_AD0	GPMC0_AD0	Disable	NA	0	Enable	0	PADCONFIG15
GPMC0_AD1	GPMC0_AD1	Disable	NA	0	Enable	0	PADCONFIG16

Table 5-32. GPMC NOR Boot Pin Usage (continued)

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_BE0n_CLE	GPMC0_BEOn_CLE	Disable	NA	0	Disable	0	PADCONFIG36
GPMC0_BE1n	GPMC0_BE1n	Disable	NA	0	Disable	0	PADCONFIG37
GPMC0_CSn0	GPMC0_CSn0	Disable	NA	0	Disable	0	PADCONFIG42

Note

Only 21 address lines (GPMC0_A0 – GPMC0_A20) are used because the GPMC0_A21 and GPMC0_A22 lines are muxed with GPMC0_WAIT1 and GPMC0_WPn respectively.

GPMC0_A20 is muxed with GPMC0_CSn3, and ROM uses GPMC0_A20 for this address line. Thus, no CSn3 support when using GPMC NOR boot.

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.8.1 GPMC NOR Bootloader Operation

In this mode, the ROM Code configures the GPMC interface based on the configuration parameters specified in the boot parameter table for the GPMC NOR boot mode Section 5.6.11, see*GPMC NOR Boot Parameter Table*.

Timing registers are programmed as follows for NOR flash boot:

Table 5-33. GPMC NOR Timing Configuration

GPMC register	Value
GPMC_CONFIG1	0x00001010
GPMC_CONFIG2	0x00101c01
GPMC_CONFIG3	0x23060917
GPMC_CONFIG4	0x1005bc1a
GPMC_CONFIG5	0x011b111e
GPMC_CONFIG6	0x8f070000
GPMC_CONFIG7	0x00000c50

GPMC NOR boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it. Only non-muxed memory is supported. If the initial image at offset 0x0 is not recognized, the ROM will attempt to read a redundant image from offset 0x100000. This is the only redundant image supported by the ROM.

Copyright © 2024 Texas Instruments Incorporated

5.4.9 GPMC NAND Boot

Table 5-34 summarizes the GPMC pin configuration done by ROM code for NAND boot.

Table 5-34. GPMC NAND Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_AD0	GPMC0_AD0	Disable	NA	0	Enable	0	PADCONFIG15
GPMC0_AD1	GPMC0_AD1	Disable	NA	0	Enable	0	PADCONFIG16
GPMC0_AD2	GPMC0_AD2	Disable	NA	0	Enable	0	PADCONFIG17
GPMC0_AD3	GPMC0_AD3	Disable	NA	0	Enable	0	PADCONFIG18
GPMC0_AD4	GPMC0_AD4	Disable	NA	0	Enable	0	PADCONFIG19
GPMC0_AD5	GPMC0_AD5	Disable	NA	0	Enable	0	PADCONFIG20
GPMC0_AD6	GPMC0_AD6	Disable	NA	0	Enable	0	PADCONFIG21
GPMC0_AD7	GPMC0_AD7	Disable	NA	0	Enable	0	PADCONFIG22
GPMC0_ADVn_ALE	GPMC0_ADVn_ALE	Disable	NA	0	Disable	0	PADCONFIG33
GPMC0_OEn_Ren	GPMC0_OEn_Ren	Disable	NA	0	Disable	0	PADCONFIG34

5.4.9.1 GPMC NAND Bootloader Operation

Timing registers are programmed as follows for NAND flash boot:

Table 5-35. GPMC NAND Timing Configuration

GPMC register	Value
GPMC_CONFIG1	0x00000813
GPMC_CONFIG2	0x00080b00
GPMC_CONFIG3	0x22080810
GPMC_CONFIG4	0x05006890
GPMC_CONFIG5	0x0107080b
GPMC_CONFIG6	0x80000180
GPMC_CONFIG7	0x00000f50

GPMC NAND boot only supports boot from ONFI 1.0 compatible 8 bit parallel NAND memory up to 2Gbytes in size connected to GPMC CS0 with the following geometries:

- 2Kbyte page and spare area of at least 64 bytes or
- 4Kbyte page size and spare area of at least 128 bytes.
- Non-ECC part only:
  - ROM uses ELM to handle ECC
  - ECC is BCH8 using D[7:0] for data
  - The param page CRC is checked and in case of failure the redundant page is used

GPMC is setup to comply with mode 0 timing for NAND flash.

5.4.10 Serial NAND Boot

Serial NAND Configuration Fields table shows configuration pins assignment to functions when boot mode is Serial NAND.

Table 5-36. Serial NAND Configuration Fields

BOOTMODE Pins	Field	Value	Description
8	Read Mode 2	0	Reserved (Read mode is taken from Read Mode 1
		1	SPI/ 1-1-1 mode (Read mode is taken from Read Mode 2 and Read Mode 1 is ignored)
7	Read Mode 1	0	OSPI/ 1-1-8 Mode (valid only when Read Mode 2 is 0)
		1	OSPI/ 1-1-4 Mode (valid only when Read Mode 2 is 0)

Serial NAND Pin Usage table summarizes the pin configuration done by ROM code for the Serial NAND device.

Table 5-37. Serial NAND Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_LBCLKO	OSPI0_LBCLKO	Disable	NA	0	Enable	0	PADCONFIG1
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.10.1 Serial NAND Bootloader Operation

Serial NAND defines 1S-1S-1S mode for general backwards compatibility, and 1S-1S-8S for maximum throughput (S here means *S*ingle Data rate). Serial NAND memory array is organized into pages of size 2KB/4KB. Read is a two-step process where a complete page is first read into flash's internal buffer/cache using Page read command and then the host controller reads from internal buffer in 1- or 4- or 8-bit mode using the read commands. Page read command that is issued is 0x13, followed by 24 address bits. The frequency of operation supported is 50 MHz.

For 1S-1S-1S mode of operation (Bit-width =1, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x0B, followed by address bits and 8 dummy cycles.

For 1S-1S-8S mode of operation (Bit-width =8, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x8B, followed by address bits and 8 dummy

Copyright © 2024 Texas Instruments Incorporated

cycles. Additionally, flash is configured in 8-bit mode after POR through volatile configuration register if the manufacturer is Winbond.

For 1S-1S-4S mode of operation (Bit-width =4, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x6B, followed by address bits and 8 dummy cycles. Note that in 8-bit mode pin mux is done for all 8 OSPI data lines and in 4-bit/1-bit mode pin mux is done for 4 OSPI data lines. This is done to disable the HOLD functionality feature in 1-bit mode.

Serial NAND boot expects ECC to be auto-managed by the flash. Most of the flashes have the ECC enabled by default and can do 1-bit correction and 2-bit detection for ECC errors. ROM checks for 2-bit ECC error via status register 3 (address 0xC0) bit 5 after every page load. In case of 2-bit ECC error the boot will fail and ROM will take the fallback option.

Serial NAND boot also manages bad blocks that can be present in the flash at time of shipment or develop during the lifetime. Bad block marker is a non-FFh data byte stored at Byte 0 of spare area of Page 0 for each bad block and ROM checks for the same while reading the first page of a memory block. ROM will skip the particular block if it is marked as bad and move to the next one.

The Serial NAND driver in ROM does not support devices that have multiple planes as they require special handling to read even numbered blocks

5.4.10.2 Serial NAND Initialization Process

In the OSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the OSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See Section 5.4.1.1, *OSPI Boot Device Configuration* for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI Boot Parameter Table*.

5.4.10.3 Serial NAND Loading Process

OSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2024 Texas Instruments Incorporated

5.4.11 No boot/Development boot

Table 5-38 shows configuration pins assignment to functions when boot mode is the No-boot mode.

Table 5-38. No-boot/Dev-boot Configuration Fields

Field	Value	Description
No/Dev	0	Development Boot
	1	No boot
ARM/Thumb	0	ARM mode
	1	Thumb mode

These boot modes are useful for debugging purposes to preclude the execution of the ROM.

During the Development boot (BOOTMODE[7] = 0), the SMS M4F ROM code will act as if boot of the primary image has completed, and the SMS M4F ROM then will be waiting for a firmware load message from DM R5. Thus the user can load a standard u-boot/SPL image to the DM R5 RAM. U-boot/SPL will then load the SMS firmware and complete the full boot.

In No-boot (BOOTMODE[7] = 1), both the SMS M4F and DM R5 ROMs are bypassed and both CPUs are held in a dummy branch-to-self loop. No-boot is the most minimal device touch state by the ROM - only minimal hardware configurations are done and none of the PLLs is locked/configured. No-boot is suitable if user wants to load his own PLL, Pad config, and other basic settings.

Copyright © 2024 Texas Instruments Incorporated

5.5 PLL Configuration

ROM code must be aware of the reference clock provided to PLLs. That is, the speed of the quartz crystal, or the clock supplied by an external clock oscillator. On how to indicate the PLL reference clock, see PLL Reference Clock Selection

ROM code configures only PLLs which are required during boot. Therefore, if a PLL is required for the backup boot mode but not the primary boot mode, and if the backup boot mode never executes, then the PLLs required for backup boot are not enabled.

The following tables show the HSDIV values that are programmed by the R5 ROM if a boot mode uses it. A value of NA means that the ROM does not program that HSDIV

Table 5-39. MAIN_PLL0 (MAIN PLL) (2000MHz)

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	4	500	MAIN SYSCLK0
0	HSDIV1	10	200	OSPI
0	HSDIV2	0	NA	WKUP_CLKOUT
0	HSDIV3	15	133	GPMC NOR/GPMC NAND
0	HSDIV4	0	NA	MCAN
1	HSDIV5	5	200	eMMC0
1	HSDIV6	0	NA	CPTS
1	HSDIV7	4	250	TIMER
1	HSDIV8	0	NA	USB0
1	HSDIV9	0	NA	PRUSS

Table 5-40. MAIN_PLL1 (PER0 PLL) (1920MHz)

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	10	192	UART
0	HSDIV1	12	160	UART
0	HSDIV2	0	NA	WKUP_CLKOUT
0	HSDIV3	0	NA	TIMER
0	HSDIV4	0	NA	Reserved
1	HSDIV5	0	NA	OSPI
1	HSDIV6	0	NA	McASP

Table 5-41. MAIN_PLL2 (PER1 PLL) (2000MHz)

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	0	NA	PRUSS core
0	HSDIV1	8	250	CP_GEMAC
0	HSDIV2	10	200	eMMC1
0	HSDIV3	0	NA	DebugSS
0	HSDIV4	0	NA	GPU
1	HSDIV5	0	NA	PRUSS IEP
1	HSDIV6	0	NA	TIMER
1	HSDIV7	0	NA	GPMC
1	HSDIV8	0	NA	McASP
1	HSDIV9	0	NA	WKUP_CLKOUT

Copyright © 2024 Texas Instruments Incorporated

Table 5-42. MAIN_PLL15 (2000MHz)

HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
HSDIV0	5	400	HSM/SMS/DM
HSDIV1	5	400	SA3_UL PKA

Note

All other PLLs are not used or programmed by the ROM

Note

The bringup and configuration of bootmode-specific PLLs by ROM code will result in a bootmode-specific device clocking setup which for example has an impact on which peripheral modules can readily be clocked and used by SBL/SPL prior to loading and bringing up System Firmware (SYSFW)

Copyright © 2024 Texas Instruments Incorporated

5.6 Boot Parameter Tables

The boot parameter tables direct the main module boot process. On cold boot the tables are created based on pin strapped values (see Section 5.3, *Boot Mode Pins*) and built-in data. The ROM Code supports two parameter tables stored as an array in a fixed memory address in the internal RAM, each of size 512 bytes. The ROM will attempt to boot using the primary table. On boot failure, ROM Code will retry using the second table.

Using two tables handles two cases.

- The first is in initial board manufacture where the primary boot table specifies boot from a flash device, and the flash is blank. ROM Code would then switch to the secondary boot mode which would receive the image externally (Ethernet, USB, UART) and this image would flash the boot image.
- The second case is failure due to total flash corruption. In flash parameter tables, there exists backup addresses within the primary boot mode. This covers the problem of a flash update failure with a backup image present on the same flash device. Note for SD Card/eMMC boot, the backup addresses are only applicable in raw boot mode

The boot tables reside at a fixed location in memory which is described in Section 5.8.1, *Global Memory Addresses Used by ROM Code*.

5.6.1 Common Header

These boot parameter tables have certain parameters common across all the boot modes, while the rest of the parameters are unique to the boot modes. The common entries in the boot parameter table are shown in Table 5-43.

Table 5-43. Boot Parameter Table Common Header

Byte Offset	Size (bytes)	Name	Description
0	2	Length	The length of the table
2	2	Checksum	Ones complement checksum over length bytes in the table. If 0 the checksum is not validated.
4	2	Peripheral	Identifies the boot peripheral and format of the table after the common header. See Table 5-44
6	2	Reserved	Reserved
8	4	Timeout	Timeout for this boot mode, in milliseconds
12	4	Magic	Magic value 0x01AD0911
16	40	PLL Config 0	PLL Configuration 0. See Table 5-45
56	40	PLL Config 1	PLL Configuration 1
96	40	PLL Config 2	PLL Configuraiton 2
136	40	PLL Config 3	PLL Configuration 3
176	40	PLL Config 4	PLL Configuration 4
216	40	PLL Config 5	PLL Configuration 5

Table 5-44 lists the possible boot modes used in the boot parameter tables.

Table 5-44. Boot Peripheral Selection

Peripheral Field Value	Description
0	Sleep (No boot)
10	Ethernet Reserved
20	Ethernet BOOTP/TFTP (general)
21	Ethernet RGMII specific
22	Ethernet RMII specific
30	Reserved
31	Reserved
32	Reserved

101	eMMC (general)
102	MMC 1-bit
103	MMC 4-bit
104	MMC 8-bit
110	GPMC NOR
120	Reserved
130	xSPI
140	GPMC NAND

5.6.2 PLL Setup

Table 5-45 through Table 5-49 describe the PLL configuration fields.

Table 5-45. Boot Parameter Table PLL Configuration

Byte Offset	Size (bytes)	Name	Description
0	1	Domain/cfg	See Table 5-46
1	1	Pll number	PLL number indexed from 0.
2	1	Input source	See Table 5-48
3	1	Pll Type	This field must be 1 to indicate an SCPLL
4	4	Input Ref Clock	The PLL input clock, in Q16.16 format
8	4	Feed back divider, integer part	Integer value of feedback divider
12	4	Feed back divider, fractional part	Fractional portion of feedback divider. Total divider is the Integer part + (Fractional part / 2^{24})
16	1	Ref divider	Input clock pre-divider
17	1	Post divider 1	Output post divider 1
18	1	Post divider 2	Output post divider 2
19	1	Reserved	Reserved
20	2	Hsdiv Enable	Bit map. A set bit indicates that the corresponding hsdiv is enabled.
22	2	Reserved	Reserved
24	16	Hsdiv[16]	Array of hs divider values.

Table 5-46. PLL Domain and Enable Configuration

Table 5-47. PLL Domain and Enable Field Description (continued)

Field	Value	Description
	1	PLL enabled only if currently disabled or in bypass
	2	PLL is unconditionally enabled. If currently enabled with a different configuration the PLL is first disabled
	3	PLL is unconditionally disabled
Domain	0	PLL is in the MCU domain
	1	PLL is in the MAIN domain

Table 5-48. PLL Reference Source Bit Fields

7	6	5	4	3	2	1	0
Source Type			Source Index				

Table 5-49. PLL Reference Source Field Description

Field	Value	Description
Source Type	0	Source is HFOSC
	1	Source is external pin
	2	Reserved
	3-7	Reserved
Source Index	0-31	Source index (HFOSC[0-31] or pin[0-31], depending on Source Type) HFOSC[0] – WKUP_HFOSC0 PIN[1] – EXT_REFCLK1 pin (not all PLLs, see Section 6.4, *Clocking*

5.6.3 OSPI/QSPI/SPI Boot Parameter Table

Table 5-50 shows the boot parameter table for OSPI, QSPI, or SPI boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-50. OSPI/QSPI/SPI Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 2, 4, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 2, 4, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 2, 4, 8)
261	1	Address Size	24	24, and 32 bits are the valid address sizes
262	1	Mode	0	OSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	Reserved	0	Reserved
270	2	Module Freq	0	The OSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The OSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command

Copyright © 2024 Texas Instruments Incorporated

Table 5-50. OSPI/QSPI/SPI Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
280	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
284	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
288	4	notDAC	From pins	When 0, DAC mode is used
292	4	Read Index	0	Index to the active read address (0-1)
296	4	Read Addr 0	0x000000	The initial flash read address
300	4	Read Addr 1	0x400000 (0x4000 SPI)	Backup read address
304	4	Reserved	0	Reserved
308	4	Reserved	0	Reserved

5.6.4 UART Boot Parameter Table

Table 5-51 shows the boot parameter table for UART boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-51. UART Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Magic	0x49	Required Magic value
257	1	Protocol	63 (0x3F)	Specifies the transfer protocol = XMODEM
258	2	Reserved	0	Reserved
260	1	Max error Count	10	Error count resulting in boot abort
261	1	Ack timeout	3	Timeout in seconds on ack
262	1	Char timeout	20	Inter-character timeout in milliseconds
263	1	Reserved	0	Reserved
264	4	Port	From Pins	Physical port number
268	4	Mod Ref Clk	48000	Module reference clock, in kHz
272	4	Data Rate	115200	Baud rate (bps)
276	1	Parity	0	0=none, 1=odd, 2=even
277	1	Data bits	8	Only 8 data bit width is supported
278	1	Stop bits	2	Stop bits in Q7.1 format (2 = 1 stop bit)
279	1	Flow Control	0	0=none, 1= RTS/CTS
280	1	Over sample	16	Only 16× and 13× oversample are supported
281	1	Magic 2	0xB7	Required magic value

5.6.5 I2C Boot Parameter Table

Table 5-52 shows the boot parameter table for I2C boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-52. I2C Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode	From Pins	0x4E = I2C Controller, 0x72 = I2C target
258	1	Dev Addr	From Pins	I2C address when target mode (0x10 or 0x11)
259	1	Reserved	0	Reserved

Copyright © 2024 Texas Instruments Incorporated

Table 5-52. I2C Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
260	4	Mod Clock	0	I2C Module input clock. If 0, it is computed by ROM code.
264	2	Bus Freq	400	I2C Controller mode bus frequency, in kHz
266	2	Bus Addr	From Pins	I2C Controller mode storage device's address (0x50 or 0x51)
268	2	Read Index	0	Index to the active read offset (0 or 1)
270	2	Read Offset 0	0x0000	I2C Controller mode read offset
272	2	Read Offset 1	0x8000	I2C Controller mode backup read offset
274	2	Reserved	0	Reserved
276	2	Reserved	0	Reserved
280	2	Busy Timeout	From pins	Number of µs before a bus recovery is attempted. In units of microseconds in Q3 number format. Value of 0 disables bus recovery attempts.

5.6.6 MMCSD/eMMC Boot Parameter Table

MMCSD/eMMC Boot Parameter Table shows the boot parameter table for eMMC, MMC or SD card boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-53. MMCSD/eMMC Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	From Pins	Physical port number
257	1	eMMC	From Pins	0 = SD/MMC, else eMMC
258	1	bootAck	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode the controller expects a boot ack from the eMMC
259	1	Media	1 for eMMC 0 for SD/MMC	0 = auto detect card type 1 = MMC 2 = SD
260	1	busWidth	8 for eMMC From Pins for SD/MMC	Number of data pins (1, 4, or 8). If 0, max supported pins of the port are used.
261	1	bootAlt	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode, the controller uses the alt boot method (CMD1 with arg 0xFFFF_FFFA) to initiate data transfer
262	1	sigVolt	0x18 for port0 0x33 for port1	Sets the signal voltage for the controller. 0x18 = 1.8V 0x33 = 3.3V
263	1	Reserved	0	Reserved
264	4	Max Bus Freq	0	Max bus frequency in kHz. If 0, the value is determined by reading the CSD register from the card (still maxes out at 25 MHz)
268	4	refClkkHz	0	Module reference clock frequency, in kHz. If 0, the ROM code computes the value.
272	4	respTimeout	40000	The timeout period on initial card read, in milli-seconds, Q3 number format
276	128	Filename	"\tiboot3.bin"	For SD/MMC, boot filename in 16-bit Unicode characters (max 64)
404	4	Mode	0x1144D091	0x1144D091 = file system boot 0x1144C180 = raw image boot
408	4	CardIsInit	0	0 = card not yet initialized 1 = card has been initialized
412	4	Rsvd	0	Reserved
416	4	RawIndex	0	Current active read offset (0 or 1)

Copyright © 2024 Texas Instruments Incorporated

Table 5-53. MMCSD/eMMC Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
420	4	Rsvd	0	Reserved
424	4	Raw Offset 0	0x000000	Raw read offset
428	4	Raw Offset 1	0x400000	Backup raw read offset
432	4	Rsvd	0	Reserved
436	4	Rsvd	0	Reserved

5.6.7 Ethernet Boot Parameter Table

Table 5-54 is shown segmented into four sections:

1. The first section contains information required to configure the device hardware
2. The second section contains information used by the top level Ethernet module to execute the boot
3. The third section contains information for the Ethernet stack code.
4. The fourth section contains information for creating the BOOTP packet (vendor string, ID string and debug string), and holds information returned in the BOOTP response (Default route and file name)

Table 5-54 shows the boot parameter table for Ethernet boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-54. Ethernet Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
Hardware Configuration Options				
256	2	Mod Freq	0	Module clock frequency, kHz. If 0, ROM code computes the value.
258	1	Port Num	0	Physical port number
259	1	Interface	From Pins	0 = RGMII with internal delay 1 = RGMII with external delay 2 = RMII
260	1	Init Level	0	0 = Initialize only not enabled modules 1 = Full ethernet sub-system initialization
261	1	Clock out enable	From pins	0x10 = CLKOUT0 enable 0x11 = CLKOUT0 disable
262	1	Clk out freq	From pins	0x20 = CLKOUT0 25 MHz (RGMII) 0x21 = CLKOUT0 50 MHz (RMII)
263	1	RMII Clk In	From pins	0x60 = RMII internal (SoC) clock 0x61 = RMII external clock
264	1	Port Enable	0x01	Bit map. A set bit indicates that the corresponding physical port will be enabled
265	1	Phy Query	From pins	0x30 = speed/duplex determined from RGMII status register 0x31 = MDIO used to query PHY 0x32 = Use fixed speed/duplex values from offset 266/267.
266	1	Speed		0x40 = full speed (1Gbit for RGMII, 100Mbit for RMII) 0x41 = slow speed (100Mbit for RGMII, 10Mbit for RMII)
267	1	Duplex		0x50 = full duplex 0x51 = half duplex
Main Level Boot Control				
268	1	Bootp enable	1	0 = Image information already in this structure 1 = Use BOOTP to get boot image information
269	1	Reserved	0	Reserved
270	2	Bootp Timeout	4000	BOOTP timeout in milli-seconds
272	2	TFTP timeout	1000	TFTP timeout in milli-seconds
274	2	Bootp retries	10	Number of BOOTP retries before fail

Copyright © 2024 Texas Instruments Incorporated

Table 5-54. Ethernet Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
276	2	TFTP retries	10	Number of TFTP retries before fail
278	2	Reserved	0	Reserved
Network Stack Configuration (plus TFTP server ID)				
280	6	MAC Address	From E-fuse	MAC address of the device
286	2	Reserved	0	Reserved
288	4	Device IP	0	IP address of the device. Valid only if BOOTP not enabled
292	4	Net Mask	0	Net mask. Valid only if BOOTP not enabled
296	4	Tftp server IP	0	TFTP server IP. Valid only if BOOTP not enabled
BOOTP send and receive Information				
300	20	Vendor String	"TI K3 Bootp Boot"	BOOTP request vendor string. Valid only if BOOTP not enabled
320	9	Client ID	1-mac-address-0	Client ID. See RFC1700
329	1	ID len	7	Client ID length
330	45	Debug array	SOC ID up to size available	Debug array output
375	1	Debug len	Varies	The number of valid bytes in debug array
376	4	Next hop	0	Next hop IP address. Valid only if bootp not enabled
380	4	Default Route	0	IP default route IP address. Valid only if bootp not enabled
384	128	Boot filename	0	Boot filename. Valid only if bootp not enabled

5.6.8 xSPI Boot Parameter Table

xSPI Boot Parameter Table shows the boot parameter table for xSPI boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-55. xSPI Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 8)
261	1	Address Size	24	24 and 32 bits are the valid address sizes
262	1	Mode	0	QSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	ddrEnable	From pins	OSPI DDR mode operation
270	2	Module Freq	0	The QSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The QSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command
280	1	SFDP	From Pins	Enables SFDP parser for 1S-1S-1S to 8D-8D-8D switching

Copyright © 2024 Texas Instruments Incorporated

Table 5-55. xSPI Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
282	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
286	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
290	4	inDAC	From pins	When 0, XIP mode is used
294	4	Read Index	0	Index to the active read address
298	4	Read Addr 0	0x000000	The initial flash read address
302	4	Read Addr 1	0x400000	Backup read address

5.6.9 USB DFU Boot Parameter Table

USB DFU Boot Parameter Table shows the boot parameter table for USB DFU boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-56. USB DFU Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
264	4	Base address 1	From pins (port)	Base address of controller
268	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
272	4	modRefClkkHz	varies	Module reference clock, in kHz
276	2	Vendor ID	0x0451	USB vendor ID. Read from control registers.
278	2	Product ID	0x6165	USB product ID. Read from control registers.
280	2	BCD Device	0x200	Binary Coded Decimal device release number
284	4	String Table addr	0x4182A76C	Pointer to the string table in RAM
288	2	Vendor String offset	0	Offset to vendor string in string table
290	2	Prod string offset	32	Offset to product string in string table
292	2	Serial num string offset	64	Offset to serial number string in string table
294	2	Timeout	5000	USB timeout in milliseconds
296	2	Mode	1	1 = DFU ≠1 = MSC Mode 1 = backup DFU, 2 = backup MSC
298	1	Lane reverse	From pins	Set to non-zero for lane reverse
299	1	CoreVoltage	From pins	USB Core Voltage 0 = 0.85V, 1 = 0.75V
300	4	Block Size	4096	DFU Block Size

5.6.10 USB MSC Boot Parameter Table

USB MSC Boot Parameter Table shows the boot parameter table for USB boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-57. USB MSC Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
264	4	Base address 1	From pins (port)	Base address of controller
268	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
272	4	modRefClkkHz	varies	Module reference clock, in kHz

Copyright © 2024 Texas Instruments Incorporated

Table 5-57. USB MSC Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
276	2	Vendor ID	0x0451	USB vendor ID. Read from control registers.
278	2	Product ID	0x6164	USB product ID. Read from control registers.
280	2	BCD Device	0	Binary Coded Decimal device release number
284	4	String Table addr	0x4182BCA8	Pointer to the string table in RAM
288	2	Vendor String offset	0	Offset to vendor string in string table
290	2	Prod string offset	0	Offset to product string in string table
292	2	Serial num string offset	0	Offset to serial number string in string table
294	2	Timeout	5000	USB timeout in milliseconds
296	2	Mode	1	1 = DFU ≠1 = MSC Mode 1 = backup DFU, 2 = backup MSC
298	1	Lane reverse	From pins	Set to non-zero for lane reverse
299	1	CoreVoltage	From pins	USB Core Voltage 0 = 0.85V, 1 = 0.75V
300	64	FileName	tiboot3.bin	Boot file name

5.6.11 GPMC NOR Boot Parameter Table

Table 5-58 shows the boot parameter table for GPMC NOR boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-58. GPMC NOR Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	refClkkHz	0	The module functional clock frequency, in kHz. 0 = ROM code computes the value.
260	4	csSizeMb	64	The size of each chip-select, in MB
264	1	Csel	From pins	The chip-select to use (0-3)
265	1	adMux	From pins	The address/data multiplexing used. 0 = A/D parallel, 1 = A/A/D mux, 2 = A/D mux
266	1	Width	16	Data bus width
267	1	Reserved	0	Reserved
268	4	Read index	0	The currently active read offset (0-1)
272	4	Read offset 0	0x000000	Read address offset 0
276	4	Read offset 1	0x400000	Backup read address offset 1
280	4	Reserved	0	Reserved
284	4	Reserved	0	Reserved

5.6.12 GPMC NAND Boot Parameter Table

GPMC NAND Boot Parameter Table shows the boot parameter table for GPMC NAND boot. Must be preceded with the common boot parameters described in Table 5-43.

Table 5-59. GPMC NAND Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Ref Clk kHz	From pins	Specifies the module ref clock.
260	4	Page Size	0	Page size in bytes 2048 or 4096
264	1	Chip Select	0	Chip Select
265	1	Ad Mux	0	Address/data multiplexing

Copyright © 2024 Texas Instruments Incorporated

Table 5-59. GPMC NAND Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
266	1	Data Bus Width	8	Data bus width. Valid values are 8 and 16
267	1	AD rows	0	Number of Row address
268	1	AD columns	0	Number of Column address cycles
269	1	ECC Nibbles	0	Size of BCH remainder in nibbles. 0 if no ECC, 26 for BCH8
270	2	Current Valid Block	0xFFFF	Block number of last known good block
272	2	Pages per Block	0	Number of pages in a block
274	2	Reserved	0	Reserved
276	4	Current Read Index	0	Active read index
280	4	Read Offset[0]	0	Offsets from base of GPMC NAND memory
284	4	Read Offset[1]	0x400000	Offsets from base of GPMC NAND memory

Copyright © 2024 Texas Instruments Incorporated

5.7 Boot Image Format

5.7.1 Overall Structure

The boot image consists of an X.509 Certificate, which is optional for GP devices, followed immediately by a boot image blob.

X.509 Certificate (Variable Size) (Optional)
Boot Image Blob (Variable Size)

5.7.2 X.509 Certificate

The X.509 certificate is described in RFC5280. Section 4.1 of the specification describes the format.

The X.509 fields relevant to the public boot (taken from RFC5280) are shown below.

```
Certificate  ::=  SEQUENCE  {
        tbsCertificate       TBSCertificate,
        signatureAlgorithm   AlgorithmIdentifier,
        signatureValue       BIT STRING  }
   TBSCertificate  ::=  SEQUENCE  {
        version         [0]  EXPLICIT Version DEFAULT v1,
        serialNumber         CertificateSerialNumber,
        signature            AlgorithmIdentifier,
        issuer               Name,
        validity             Validity,
        subject              Name,
        subjectPublicKeyInfo SubjectPublicKeyInfo,
        issuerUniqueID  [1]  IMPLICIT UniqueIdentifier OPTIONAL,
                             -- If present, version MUST be v2 or v3
        subjectUniqueID [2]  IMPLICIT UniqueIdentifier OPTIONAL,
                             -- If present, version MUST be v2 or v3
        extensions      [3]  EXPLICIT Extensions OPTIONAL
                             -- If present, version MUST be v3
        }
  Extensions  ::=  SEQUENCE SIZE (1..MAX) OF Extension
   Extension  ::=  SEQUENCE  {
        extnID      OBJECT IDENTIFIER,
        critical    BOOLEAN DEFAULT FALSE,
        extnValue   OCTET STRING
                    -- contains the DER encoding of an ASN.1 value
                    -- corresponding to the extension type identified
                    -- by extnID
        }
```

In general, an X.509 certificate contains a public key which has been signed by a private key. The public ROM code does not directly use the keys. In non-secure devices, the public key value is in general a don't care condition. The exception is certificates containing a degenerate RSA public key. GP devices with a degenerate RSA key allow for integrity checking of most (but not all) of the certificate.

The public ROM only needs to extract some of information from the X.509 formatted structure:

- The total size of the X.509 Certificate
- The total size of the boot image

The total size of the X.509 Certificate is determined by reading the length of the sequence containing the certificate. The length of the image is determined by parsing the certificate to find the extension field which holds the image length.

The ROM defines several extensions that are used only by TI for boot. These are placed in the extensions field of the TBS certificate.

5.7.3 Organizational Identifier (OID)

OID (organizational identifier) values are represented as a tree structure. TI has the following node registered:

Copyright © 2024 Texas Instruments Incorporated

1.3.6.1.4.1.294: iso(1), identified-organization(3), dod(6), internet(1), private(4), enterprise(1), Texas Instruments(294)

ROM code adds the following branch after *Texas Instruments*: *device-boot(1)*. The OID values shown in this section are leaves off the device boot branch.

5.7.4 X.509 Extensions Specific to Boot

These values are not defined in any standard, but created by TI for boot.

5.7.4.1 Boot Info (OID 1.3.6.1.4.1.294.1.1)

This extension must be present on all boot images. It is from this extension that the image length is extracted.

```
bootInfo ::=  SEQUENCE {
   cert_type: INTEGER,-- identifies the certificate type
   boot_core:INTEGER,-- identifies the boot core
   core_opts:INTEGER,-- 32 or 64 bit boot core target
   load_addr:OCTET STRING,-- Global address image destination
   image_size:INTEGER,-- Image size in bytes
}
```

Table 5-60. Certificate Type Values

Value	Description
0x0000_0001	Primary boot image
0x0000_0002	Firmware image

Table 5-61. Boot Core Values

Value	Description
0x00	Firmware (M4) image
0x08	M4 certificate
0x10	R5 image
0x20	Reserved

Table 5-62. Core Options Bit Fields

31	2	1	0
Reserved		Split	Mode

Table 5-63. Core Options Field Description

Bits	Field	Value	Description
1	Split	0	Dual MCU set to lockstep (two cores in lockstep)
		1	Dual MCU set to split mode (two independent cores)
0	Mode	0	MCU starts execution in Arm® mode
		1	MCU starts execution in Thumb® mode

5.7.4.2 Image Integrity (OID 1.3.6.1.4.1.294.1.2)

```
imageIntegrity ::= SEQUENCE {
   sha_type:OID,-- Identifies the SHA type
   hash:OCTET STRING-- The SHA of the boot image
}
```

5.7.5 Extended Boot Info Extension

The ROM supports a combined boot image boot flow. In this flow, a boot binary blob has both Secondary bootloader (SBL) and System Firmware (SYS-FW) embedded in the boot image with a single X509 certificate. This method helps with the following situations:

Copyright © 2024 Texas Instruments Incorporated

- Allows ROM to load and run both the bootloader and SYS-FW in parallel without any dependency.
- Optimizes ROM boot time by minimizing different x509 certificate parsing and authentication.

To support this combined boot format, ROM employs a new X509 extension called: ext_boot_info. It supports multiple boot components with a single certificate. It allows up to 5 components as part of this extension:

- Component1: Mandatory and should point to info about SBL binary
- Component2: Optional and if present should point to SYS-FW binary in all device types
- Component3: Optional (Load section to SBL, new certType)
- Component4: Optional (Load section to SYS-FW, new certType)
- Component5:
  - HS-FS and HS-SE non Prime devices. Mandatory and should point to SYS-FW Inner certificate
  - GP and HS-SE Prime devices. Optional (Load Section to SBL or SYS-FW)

This extended boot info extension replaces boot_seq (boot_info) and image_integrity extensions from the previous sections, and these should be exclusive in any given certificate.

ROM supports other extensions, such as sw_rev and debug_info, in both formats.

ROM selects the combined image flow based on the presence of ext_boot_info extension in the certificate and skips boot_seq (boot_info) and image_integrity extensions boot flow.

Having one component in ext_boot_info is same as legacy flow (that is, flow using boot_seq and image_integrity); for two or more components, ROM starts both SBL and SYS-SW, the third and fourth components are loaded by ROM to the allowed loading memory range of SBL and SYS-FW if there is no overlap in load address with executable binary info.

Each of the components can independently specify hash value of the binary, and ROM validates the hash on HS and GP if RSA degenerate key is used for signing.

Additionally, ROM rejects the full image if hash of any single component mismatches.

5.7.5.1 Impact on HS Device

For HS devices, ROM supports encryption of images optionally when specified with the Encryption extenstion.

Encryption - Encryption of the components must be specified with a new extension called ext_boot_enc. This is an optional extension that must be specified only if any of the components are encrypted with a customer key set. Specify a component number followed by encryption extension details for ROM to decrypt the given components. This extension is used only with combined boot image format (that is, using Extended Boot Info Extension).

Prime vs Non-Prime - The main difference between HS prime and non-prime devices is the presence of the SYS-FW Inner certificate. Extended boot info extension supports both prime and non-prime devices. ROM supports SYS-FW binary as Comp#2 in all device types; for HS-SE non-prime and HS-FS devices, the SYS-FW inner certificate is expected as another optional component in #3, 4, or 5.

5.7.5.3 Certificate / Component Types

ROM supports only the following component types; all other component types will be rejected.

- CompType 0x1 for SBL binary - compType = INTEGER:1
- CompType 0x2 for SYS_FW binary - compType = INTEGER:2
- CompType 0x3 for SYS_FW Inner Certificate - compType = INTEGER:3
- CompType 0x11 for SBL Memory load section - compType = INTEGER:17

Primary Image load section, that can be loaded in to SBL allowed memory range:

- CompType 0x12 for SYS_FW Memory load section - compType = INTEGER:18

SYS-FW load section, that can be loaded in to SYS-FW allowed memory range

5.7.5.4 Extended Boot Encryption Info

Extended Boot Encryption Info specifies the imageEncryption extension per component basis. This extension is not applicable for GP or HS-FS devices, and is optional for HS-SE devices if any components in the image are encrypted. In HS-FS and HS-SE non-prime devices, the SYS-FW binary encryption details are part of SYS-FW Inner certificate. This extension is applicable if either SBL, SYS-FW binary in HS-SE prime, or any binary blobs are encrypted in HS-SE devices.

 iterationCnt = INTEGER:2
 salt = FORMAT:HEX,OCT:ccccccccccccccccccaa84f29d6b68d0
```

5.7.5.5 Component Ordering

ROM supports fixed Component ordering for SBL- Binary and SYS-FW Cert and Binary.

For GP and HS-SE Prime devices, Comp#1 should be SBL binary, and Comp#2 should be SYS-FW binary.

For HS-FS and HS-SE non-Prime devices, Comp#1 should be SBL binary, Comp#2 should be SYS-FW Inner Certificate, and Comp#3 should be SYS-FW binary.

5.7.5.6 Memory Load Sections Overlap with Executable Components

Memory load sections for SBL and SYS-FW (CompType 0x11 and 0x12) the destination address and size should not overlap with the corresponding load and execute sections, and should also fall in the allowed memory range by ROM.

5.7.5.7 Device Type and Extended Boot Extension

X509 Extension	Component	GP Device	HS-FS	HS-SE non-prime	HS-SE Prime Device
ext_boot_info	Comp#1	SBL Binary	SBL Binary	SBL Binary	SBL Binary
	Comp#2	SYS-FW binary	SYS-FW binary	SYS-FW binary	SYS-FW binary
	Comp#3	SBL mem load section	SBL mem load section	SBL mem load section	SBL mem load section
	Comp#4	SysFW mem load section	SysFW mem load section	SysFW mem load section	SysFW mem load section
	Comp#5	N/A	SysFW inner certificate	SysFW inner certificate	N/A
ext_enc_info	Comp#1	N/A	N/A1	SBL encryption	SBL encryption
	Comp#2			N/A	SYS FW encryption
	Comp#3			SBL memory load Encryption	SBL memory load encryption
	Comp#4			Sys-FW memory load encryption	Sys-FW memory load encryption
	Comp#5			N/A1	NA

1. SYS-FW encryption in HS-FS and HS-SE (non Prime) are handled in SYS-FW Inner certificate and they are not part of the extended boot info extensions.

5.7.6 Generating X.509 Certificates

X.509 Certificates are generated using OpenSSL and a configuration script to supply values in the extension fields.

5.7.6.1 Key Generation

The SBL must always be signed with a given OpenSSL key - Secure and GP devices. Secure must have encryption and authentication, GP device must only have authentication. The key used for authentication can be random or specific. If a random key is generated and SBL is signed with this,the ROM will copy the SBL image for authentication using memcopy. With this key, ROM code will be directed to use DMA to load the SBL for authentication which saves boot time.

Copyright © 2024 Texas Instruments Incorporated

5.7.6.1.1 Degenerate RSA Keys

Degenerate RSA keys are valid RSA keys with the private exponent set to 1. This results in the signature field being equal to the digest, since in RSA:

$$\text{Signature} = \text{digest}^{\text{privExp}} \bmod \text{n} \bmod \text{n}^{\text{privExp}} \quad (1)$$

Where n is the key size. Since the hash used is SHA-512 and the signature is an ASN.1 sequence containing the OID defining which has was used as well as the hash value, the degenerate RSA must have a value of n greater than the maximum digest size. Typically 1024-bit is chosen.

The following sequence is used to generate degenerate RSA keys:

1. Create a random RSA key:

```
openssl genrsa –out key.pm 1024
```

2. Convert to text:

```
openssl rsa –in key.pem –text –noout > key.txt
```

3. Create an asn1 template for the degenerate key called degenerateKey.txt. Simply copy the values for modulus, prime (listed as p in key.txt), prime 2 (listed as q), and coefficient (listed as coeff). Set the public and private key exponents to 1, as well as the values for e1 and e2. See the example below.
4. Convert the template to DER:

```
openssl asn1parse -genconf degenerateKey.txt -out degenerateKey.der
```

5. Sanity check the key:

```
 openssl rsa –in degenerateKey.der –inform der -text -check
```

6. If there are no errors create the degenerate key pem file:

```
openssl rsa –in degenerateKey.der –inform der –outform pem -out degenerateKey.pem
```

An example degenerateKey.txt file is shown.

```
asn1=SEQUENCE:rsa_key
[rsa_key]
version=INTEGER:0
modulus=INTEGER<copied from key.txt>
pubExp=INTEGER:1
privExp=INTEGER:1
p=INTEGER:<copied from key.txt>
q=INTEGER<copied from key.txt>
e1=INTEGER:1
e2=INTEGER:1
coeff=INTEGER<copied from key.txt>
```

Note that when copying the multi-byte fields from key.txt it is necessary to remove the colons, catenate the lines and add a preceding 0x.

5.7.6.2 Configuration Script

An example openssl configuration script is shown below. Not all extensions are required, but all possible are shown.

```
[ req ]
distinguished_name = req_distinguished_name
x509_extensions = v3_ca
prompt = no
dirstring_type = nobmp
[ req_distinguished_name ]
C = GB
ST = HI
```

pll1_num = INTEGER:1
pll0_cfg = FORMAT:HEX,OCT:00345678900
[ debug ]
uid = FORMAT:HEX,OCT:00345678900
type = INTEGER:1
dbgE = INTEGER:0
secDbgEn = INTEGER:0
```

The certificate is then generated using the following openssl command:

```
openssl req -new -x509 -key <private_key_pem_file> -nodes -out <output_X.509_pem_file> -config
<config_file> -sha512
```

If a delegate key is being signed, then add the option -signkey <sign_key_pem_file> to the command above.

5.7.6.3 Image Data

The image data (blob) is considered simply as a byte stream. On devices that are multiple bytes wide the image must be formatted so that all multi-byte fields match the endianness of the device. The R5 will always run in little endian mode.

5.8 Boot Memory Maps

5.8.1 Global Memory Addresses Used by ROM Code

The ROM code uses several global memory addresses that are useful for debugging. They are shown in Table 5-64.

Table 5-64. Global Memory Addresses

Group	Address	Size (bytes)	Content
SMS0_HSM_SRAM0_0	0x43c00000	0x3e000	Loadable memory space for SBL
Warning/Error logs	0x43c3e480	0x200	Warning Entries
Warning/Error logs	0x43c3e680	0x200	Severe Entries
Warning/Error logs	0x43c3e880	0x100	Critical Entries
Warning/Error logs	0x43c3eb80	0x14	Circular message buffer
Warning/Error logs	0x43c3eb98	0x50	Boot log context
Trace	0x43c3ebe8	0x18	Boot trace context
Trace	0x43c3ec00	0x400	Boot trace entry buffers
Parameter tables	0x43c3f290	0x4	Parameter tables index for R5 bootloader
Parameter tables	0x43c3f298	0x400	Boot Parameter table for R5 bootloader
Parameter tables	0x43c3f1e0	0xb0	Extended boot data for R5 bootloader

The ROM code version information is a structure shown in Table 5-65

Table 5-65. ROM Code Version

Chapter 6

Device Configuration

This chapter describes the device configuration details including information related to Control MMR's, Power, Reset, and Clocking.

6.1 Memory Mapped Control Register Modules (CTRL_MMR) 528
6.2 Power 533
6.4 Clocking 614

Copyright © 2024 Texas Instruments Incorporated

6.1 Memory Mapped Control Register Modules (CTRL_MMR)

This chapter covers three categories of device level control register modules:

- General-Purpose Control Register Modules
- Pad Configuration Register Modules
- Security Control Register Modules

Each category of module is described in its own section, along with detailed register descriptions for each module.

Copyright © 2024 Texas Instruments Incorporated

6.1.1 General Purpose Control Register Modules

The following sections describe the CTRL_MMR0 and PADCFG_CTRL0_CFG0 modules.

6.1.1.1 General Purpose Control Register Modules Overview

There are three General Purpose Control Register Modules on the Device:

- CTRL_MMR0 for the MAIN domain
- WKUP_CTRL_MMR0 for the WKUP domain
- MCU_CTRL_MMR0 shared between the WKUP and MCU domains, with Parity Protection.

Note

Some features may not be available. See *Module Integration* for more information.

Copyright © 2024 Texas Instruments Incorporated

6.1.1.2 General Purpose Control Register Modules Functional Description

6.1.1.2.1 Description for General Purpose Control Register Module Register Types

The following sub-sections provide summary and description for most of the registers which are part of the CTRL_MMR0, WKUP_CTRL_MMR0 and MCU_CTRL_MMR0 modules memory spaces. The rest of the registers are described in the corresponding chapters where the functionality associated with particular register is covered in more detail.

6.1.1.2.1.1 Kick Protection Registers

General Purpose Control Register Modules (and also Pad Configuration Register Modules) are organized into different partitions. Partitions can be locked to prevent unintended changes to the register value that might occur due to uncontrolled or malfunctioning software.

Each partition has two registers associated with partition locking - LOCKi_KICK0 and LOCKi_KICK1 registers are used for this purpose. A write is required first to the LOCKi_KICK0[31-1] KEY field and then to the LOCKi_KICK1[31-0] KEY field with exact data values to unlock the protection mechanism. Once released then all registers within Partition "i" having write permissions can be written to. The read only registers are still read only. An indication for unlocked Partition "i" is when the LOCKi_KICK0[0] UNLOCKED bit is set to 1h. When the protection mechanism is locked (indicated by LOCKi_KICK0[0] UNLOCKED = 0h) none of the registers within Partition "i" can be written to. They can only be read..

The key values for all partitions are:

- LOCKi_KICK0 Key: 68EF 3490h
- LOCKi_KICK1 Key: D172 BC5Ah

Writing any other data value to either of these registers locks the protection mechanism and blocks any writes to the registers that reside in Partition "i".

6.1.1.2.1.2 I/O Debounce Control Registers

Some device pads have debounce logic. The following MCU_CTRL_MMR0 registers are used to configure the debounce period:

- MCU_CTRL_MMR_DBOUNCE_CFG1
- MCU_CTRL_MMR_DBOUNCE_CFG2
- MCU_CTRL_MMR_DBOUNCE_CFG3
- MCU_CTRL_MMR_DBOUNCE_CFG4
- MCU_CTRL_MMR_DBOUNCE_CFG5
- MCU_CTRL_MMR_DBOUNCE_CFG6

The MCU_CTRL_MMR_DBOUNCE_CFG1 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE_SEL fields set to 1h. The MCU_CTRL_MMR_DBOUNCE_CFG2 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE_SEL fields set to 2h and so on. The MCU_CTRL_MMR_DBOUNCE_CFG6 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE_SEL fields set to 6h.

Note

The debounce logic is not associated with all signals that can be multiplexed on a pad. Only certain signals can use it.

For information about each signal that has associated debounce logic, see the device Datasheet.

For information about the PADCONFIGx registers, see PADCFG_CTRL Registers.

Debounce Period Values shows the debounce period values to load in the MCU_CTRL_MMR_DBOUNCE_CFGx[5-0] DB_CFG field.

Copyright © 2024 Texas Instruments Incorporated

Note

The debounce clock selection should happen before the consumer of the debounced signals is enabled as the clock multiplexers for the debounce logic are NOT glitch-free.

Table 6-1. Debounce Period Values

MCU_CTRL_MMR_DBOUNCE_CFGx[5-0] DB_CFG Decimal Value	GPIO Case (32.768kHz [1])	EQEP Case (20MHz[1])	MCU_CTRL_MMR_DBOUNCE_CFGx[5-0] DB_CFG Decimal Value	GPIO Case (20MHz[1])	EQEP Case (250MHz[1])

6.1.2 Pad Configuration Register Modules

The following sections describe the CTRL_MMR0 and PADCFG_CTRL0_CFG0 modules.

6.1.2.1 Pad Configuration Register Modules Overview

There are three General Purpose Control Register Modules on the Device:

- PADCFG_CTRL0 for the MAIN domain
- MCU_PADCFG_CTRL0 for the MCU and WKUP domains

Note

Some features may not be available. See *Module Integration* for more information.

Copyright © 2024 Texas Instruments Incorporated

6.1.3 Security Control Register Modules

The following sections describe the CTRL_MMR0 and PADCFG_CTRL0_CFG0 modules.

6.1.3.1 Security Control Register Modules Overview

There are two Security Control Register Modules on the Device:

- MAIN_SEC_MMR0 for the MAIN and MCU domains
- WKUP_SEC_MMR0 for the WKUP domain

6.2 Power

This chapter describes the power-management architecture implemented in the device.

6.2.1 Power Management Overview

To provide a versatile architecture that supports multiple power-management techniques, the power management framework is built with three levels of resource management: clock, power, and voltage.

These management levels are enforced by defining the managed entities or building blocks of the power management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch).

To minimize device power consumption, the clocks can be gated (turned off), or the power to the modules can be switched off, when they are not in use. Independent power and clock control of sections of the device allows for turning on and off specific sections of the device without affecting other sections.

6.2.2 Power Control Modules

The Power Control Modules are divided into two sections, dependent on their functionality - Power Sleep Controller section and Device Manager section.

6.2.2.1 Power Sleep Controller

6.2.2.1.1 PSC Architecture

Power Sleep Controller (PSC) is a control component to manage the power domain and module's clock and reset transition. Each PSC module contains multiple power domains, within each power domain, it can contain multiple LPSC. Each LPSC can be used to manage the one or multiple module's reset and clock stop status, see Figure 6-1.

Each power domain has a unique index, starting from number 0. The power domain 0 is a special power domain, which is always on. The status of power domain 0 can't be changed after the device is out of reset.

Each power domain can have one or more Local Power Sleep Control (LPSC). Each LPSC in the same PSC has a unique index value as well. LPSC 0 is special, which user can't change its status. LPSC 0 is always set to be enabled after the device is out of reset.

One LPSC can be used to control the reset and clock status for one or more modules. Some of the LPSC can be used to provide local reset function for the processors, such as A53 and R5 and M4F core. LPSC can also be used to manage the clock stop interface for the interfaces between two interconnect IPs. This is mainly used for providing isolation features required by some special features such as security isolation, functional safety isolation or reset isolation between different parts of the SoC.

Copyright © 2024 Texas Instruments Incorporated

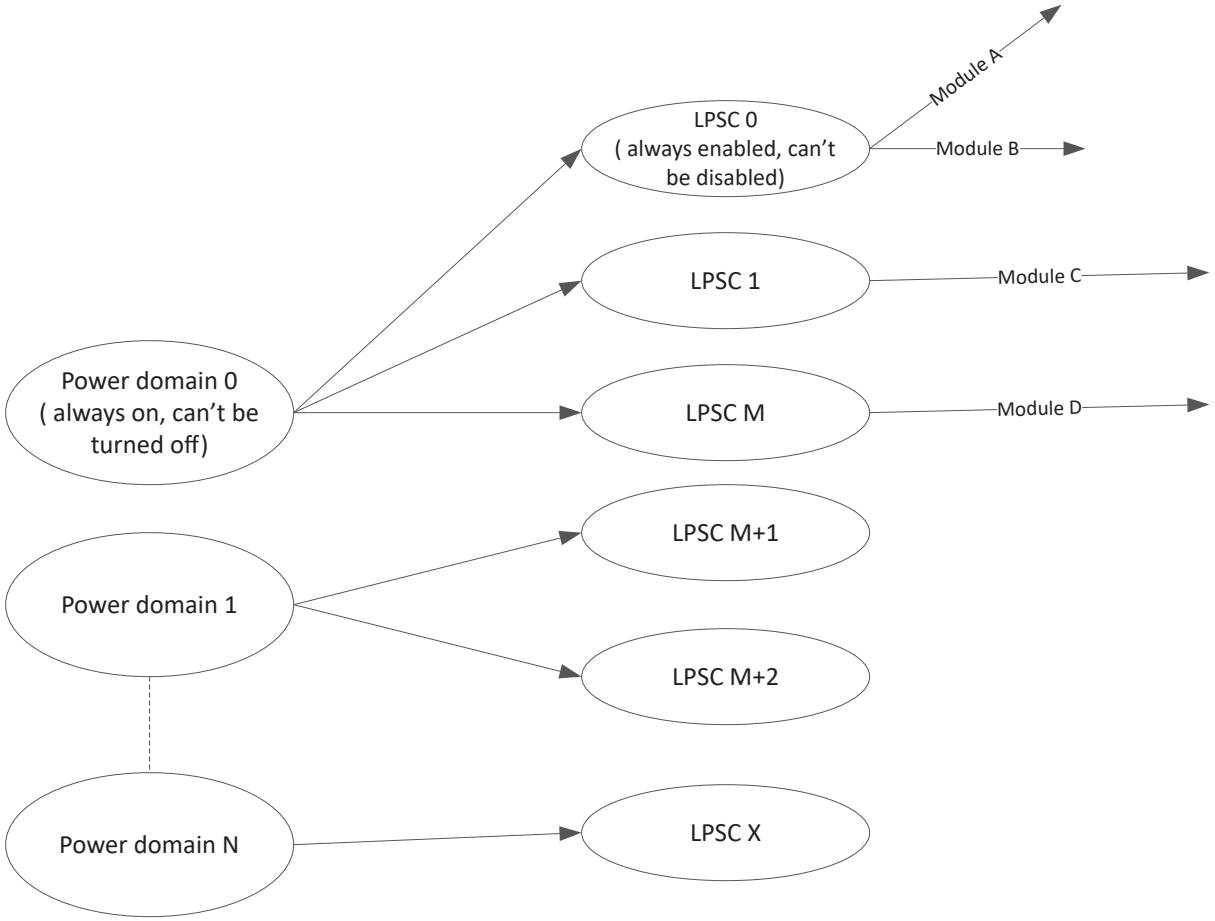

Figure 6-1. PSC Architecture

Note

PSC functions are controlled via Device Manager. For more information how to use Device Manager, see TISCI API available at ti.com.

6.2.2.1.2 PSC Configurations

Device is partition into two PSC control portions, each portion has its own dedicated PSC module: PSC0 and MCU PSC.

Table 6-2 presents Power Domain features for the processor.

Table 6-2. Power Domain Features

PSC	PD name	PD index	GP / PD	Default Power Domain State	PD State Software Controlled
MCU PSC	GP_Core_CTL_MCU	0	GP (1)	AO(3)	NO
	PD_MCU_M4F	1	PD(2)	ON	YES

Copyright © 2024 Texas Instruments Incorporated

Table 6-2. Power Domain Features (continued)

PSC	PD name	PD index	GP / PD	Default Power Domain State	PD State Software Controlled
PSC0	GP_Core_CTL	0	GP(1)	AO(3)	NO
	PD_ICSSM	1	PD(2)	OFF	YES
	PD_CPSW	2	PD(2)	ON	YES
	PD_A53_cluster_0	3	PD(2)	OFF	YES
	PD_A53_0	4	PD(2)	OFF	YES
	PD_A53_1	5	PD(2)	OFF	YES
	PD_A53_2	6	PD(2)	OFF	YES
	PD_A53_3	7	PD(2)	OFF	YES
	PD_GPU	8	PD(2)	OFF	YES
	PD_DSS	9	PD(2)	OFF	YES

(1) Group with common power - means that there are no power switches. The group is considered always-on.
(2) Power switched domain - means this is a full power switched domain.
(3) AO = Always On

Table 6-3 and Table 6-4 show the summary how each module is controlled by LPSC.

Copyright © 2024 Texas Instruments Incorporated

6.2.2.1.2.1 Software Sequence to enable an IP through PSC

In order to enable a module, user needs to program the PSC to put LPSC into enable state. There is dependence between power domain and LPSC and among different LPSC controls.

First of all, in order to enable any LPSC, the power domain which that LPSC belongs needs to be enabled first. The LPSC can't put into any state other than disable if the power domain is not enabled.

Among different LPSC, there is also a special sequence needs to be followed to make sure the device is not getting into undefined state.

Similarly, a special sequence shall be followed to disable the LPSC to prevent device getting into undefined states. Before a power domain can be turned off, all the LPSCs within that power domain shall be disabled first. Normally, user can turn off the power domain to save power. However, it is not necessary to turn off the power domain when all the LPSCs inside that power domain are disabled.

Figure 6-2 shows how to understand the dependent relationship between two LPSCs. In order to enable LPSC_2, LPSC_1 shall be enabled first.

If user wants to disable LPSC_1, LPSC_2 shall be disabled first.

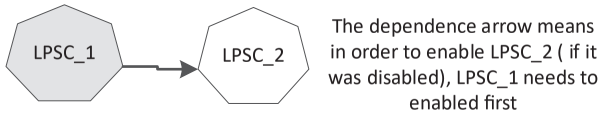

Figure 6-2. LPSC Dependence

Figure 6-3 shows the dependent relationship among all the LPSCs in the device.

6.2.2.2 Device Manager

The device has one Device Manager located in WKUP domain. Device Manager is responsible for entry/exit to low power modes. Also, Device Manager hosts RM/PM (Resource manager/power manager) SYSFW code for providing RM/PM services to HLOS. As part of boot, public ROM is executed over Device Manager.

Device Manager Features

- Single Core Cortex-R5 subsystem
  - ARMv7-R architecture with following extensions
    - Advanced SIMD extension for integer and floating-point vector operations
    - Vector Floating Point Version 3 (VFPv3)
  - L1 memory architecture
    - 32KB I-cache with 64-bit ECC error checking
    - 32KB D-cache with 64-bit ECC error checking
  - 64Kbyte TCM(L2) with 32-bit ECC error checking
  - 32-bit AXI3 initiator interface for accessing local peripherals
- 1x RTI/WWDT
- 2x Timer
- 1x UART
- 1x I2C
- Wake-up logic
- Public ROM
- RTC digital
- VTM
- LFOSC

Note

PSC functions are controlled via Device Manager. For more information how to use Device Manager, see TISCI API available at ti.com.

6.2.3 Power Management Techniques

The following section describes the power management techniques supported by the device

6.2.3.1 Dynamic Frequency Scaling (DFS)

DFS is a power management technique where the operating frequency is dynamically scaled across device Operating Performance Points (OPP). An OPP is a voltage/frequency pair that defines a specific power state. For each OPP, software controls clock frequency in order to adjust the performance and power to the optimum point. The Device supports DFS for Cortex-A53 only.

6.2.3.2 OPP Low

The device supports lower bus frequency operation as OPP Low. The OPP Low must be configured at boot time. In OPP Low, the main CBASS clock frequency is reduced in half in order to lower active power consumption with reduced performance. The performance of some peripheral modules is limited or not available in this operating condition.

Refer to the device datasheet to determine the supported features and the clock frequency of cores, modules, and peripheral I/Os in OPP Low.

6.2.4 Power Modes

The following sections describe a high-level description of the different power modes of the device. They are listed in order from highest power consumption, lowest wakeup latency (Standby), to lowest power consumption, highest wakeup latency (Partial IO). If your application requires some sort of power management, you must determine which power mode level described below satisfies your requirements. Each level must be evaluated based on power consumed and latency (the time it takes to wakeup to Active mode). Specific values are detailed

Copyright © 2024 Texas Instruments Incorporated

in the device-specific data sheet. Note that not all modes are supported by software packages supplied by Texas Instruments.

Table 6-5. Low Power Modes

Low Power Modes	Wakeup Sources	Application State and Use Case
Partial I/O	CANUART I/O Bank pins	The entire SoC is OFF except I/O pins in CANUART I/O Bank to maintain I/O wakeup capability from CANUART I/O Bank I/O pins.
DeepSleep	GP Timers, RTC Timer, UART, I2C, WKUP GPIO, I/O Daisy Chain	Core domain register information will be lost. On-chip peripheral register (context) information of core domain needs to be saved by application to DDR before entering this mode. DDR is in self-refresh. Boot ROM executes and branches to peripheral context restore for wakeup, followed by system resume. This mode is primarily used for Suspend to RAM for battery lifetime or backup operation.
MCU Only	DeepSleep wakeup events, Interrupt events supported in MCU channel	The MCU subsystem runs at the MCU PLL clock. The rest of the SoC status is the same as DeepSleep. DDR is in self-refresh. MCU can run applications with MCU domain peripherals while in this low power mode.
Standby	Any SoC interrupt event	On-chip contents are fully preserved. Any SoC interrupt event can cause a wakeup event from this low power mode. A53 and MCU M4F are in WFI or Power Down. DDR memory is in self-refresh. The device can run low-level processing with non-Wakeup/MCU domain peripherals and support wakeup from those peripherals.

Table 6-6. Voltage, Power and Clock Domain Status

Low Power Modes	Voltage Domain				Power Domain									Clocks		DDR
	VDD_CORE / VDDR_CORE	VDDS_DDR	1.8 Analog Rails	1.8V/3.3V I/O Rails	GP_Core_CTL	PD_ICSSM	PD_CPSW	PD_A53_cluster_0	PD_A53_x	PD_GPU	PD_DSS	GP_Core_CTL_MCU	PD_MCU_M4F	Main OSC	DPLLs	
Partial I/O	OFF	OFF	OFF	Partial On	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
DeepSleep	ON	ON	ON	ON	ON	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	Self-Refresh
MCU Only	ON	ON	ON	ON	ON	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON	ON	MCU DPLL locked	Self-Refresh
Standby	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	Bypass	Self-Refresh

6.2.4.1 Active

In Active mode, the supply to all voltage rails must be maintained. All power domains come up in ON state and the device is fully functional.

6.2.4.2 Standby

The device can be placed in Standby mode to reduce power consumption during low activity levels. This first level of power management allows you to maintain the device context for fast resume times. The main characteristics of this mode that distinguish it from Active mode are:

Copyright © 2024 Texas Instruments Incorporated

- All modules are clock gated except GPIOs
- PLLs may be placed in bypass mode if downstream clocking does not require full performance
- The VDD_CORE voltage level is maintained.
- Power domain may be turned off if it's not used for the contexts can be saved and restored.
- DDR memory is in low power self-refresh mode.

The above conditions result in lower power consumption than Active mode but require the user to save the switched-off power domain context to On-Chip Memory or DDR and restore the contexts to resume properly upon wakeup.

Wakeup in Standby mode is achieved using any GPIO. GPIO wakeup is possible by switching the pad to GPIO mode and configuring the corresponding GPIO bank for generating an interrupt to the Device Manager. Note that pads that do not have a GPIO muxmode (for example, USB) cannot cause these wakeups. If additional or other wakeup sources are required, the associated peripheral module clock and interconnect clock domain should remain enabled (this may require the associated PLL to remain locked) and the module must be configured appropriately for wakeup by configuring it to generate an interrupt to the Device Manager.

6.2.4.3 MCU-Only

MCU-Only can be used for low power use cases that require low-level processing during a low power mode. The status of the SoC is the same as DeepSleep, except the MCU channel is fully active to run applications with MCU channel resources and peripherals. Any interrupt event in the MCU channel can initiate a wakeup from MCU-Only and the wakeup events supported in DeepSleep can also trigger wakeup from MCU-Only.

The main characteristics of the mode which distinguish it from other low power modes are:

- Main domain status is the same as DeepSleep
- VDD_CORE power (except VDDA analog) to PLLs is turned OFF except MCU PLL
- The main oscillator is active to keep MCU channel running.
- MCU Channel is fully active to run applications with the peripherals in the channel.
- DDR memory is in low power self-refresh mode.

6.2.4.4 DeepSleep

DeepSleep mode enables lower power consumption than Standby or MCU-Only. The main characteristics of the mode which distinguish it from other higher power modes are:

- All on-chip power domains are shut off (except GP_Core_CTL and GP_Core_CTL_MPU remain ON) to reduce power leakage
- VDD_CORE power (except VDDA analog) to PLLs is turned OFF
- The main and RTC oscillators may be turned off if they're not used to keeping timers on as a wakeup source.

DeepSleep mode is typically used during inactivity when the user requires very low power while waiting for an event that requires processing or higher performance. DeepSleep is the lowest power mode which still includes DDR in self-refresh, so wakeup events do not require a full cold boot, significantly reducing wakeup latencies.

The lowest power in this mode can be achieved by disabling both oscillators when the RTC or other timer function is not required.

The main On-Chip SRAM (OCM) contents are lost because the power domain is turned OFF.

Before entering DeepSleep mode, peripheral and MPU context must be saved in the DDR. Upon wakeup, the boot ROM executes and checks to see if it has resumed from a DeepSleep state. If so, it redirects to the DDR to continue the resume process. Because the power to Always-On power domains (GP_Core_CTL and GP_Core_CTL_MU) are ON throughout DeepSleep, power to key modules such as GPIO0 and others is maintained to allow wakeup events to exit out of this mode. In addition, the Wakeup On-Chip SRAM (OCM) power is maintained to preserve information internally during DeepSleep.

Activity on wakeup peripherals via wakeup events enables the high frequency oscillator by using the oscillator control circuit. The wakeup events also interrupt the Device Manager, which controls proper enabling of power

Copyright © 2024 Texas Instruments Incorporated

domains and clocks in the PSC. See 1.4.7, Wakeup Sources/Events, for details on wakeup sources during DeepSleep and other low power modes mentioned.

6.2.4.5 Partial I/O

In Partial I/O, I/O pins and small logics in the CANUART I/O Bank are active, and the rest of the SoC is turned off. The user can use the I/O pins to aggregate multiple I/O wakeup events and toggle PMIC_LPM_EN pin to enable PMIC or discrete power solution when an I/O wakeup event is triggered. The information on the I/O wakeup event is logged in the MMR in the CANUART I/O bank and helps the software to distinguish between cold boot and wakeup to respond to the wakeup event faster.

6.2.4.6 Power States and Transitions

The Low power mode transition always starts from the active state. If the device needs to transition from one low power mode to another low power mode, it must go through the active state first. Typically, the software initiates a transition from active mode to a low power mode and a wakeup event triggers a transition from a low power mode to active.

Figure 6-4 shows the power state transition supported by the device.

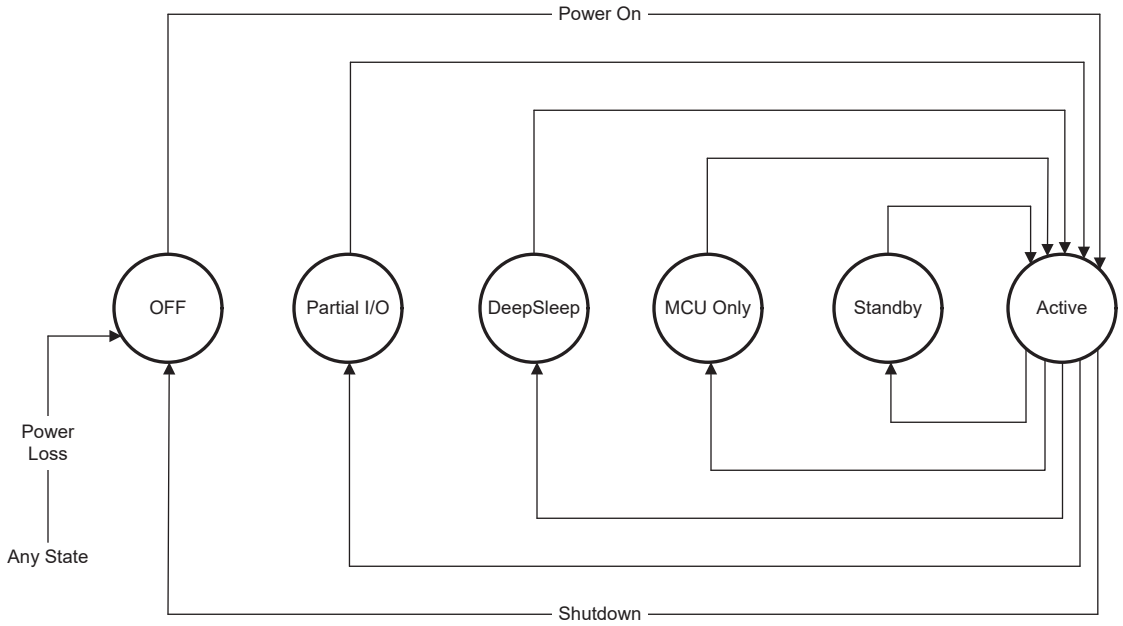

Figure 6-4. Power State Transition Diagram

6.2.4.7 Wakeup Sources/Events

Table 6-7 shows the wake sources supported in each low power mode. High-frequency or Low -frequency oscillator remains ON when a timer wakeup event is selected in DeepSleep. DeepSleep wakeup events are part of the Wakeup Power domain and remain always ON.

Table 6-7. Low Power Mode Wakeup Events

Low Power Modes	Wakeup Events
Partial I/O	CANUART I/O Bank pins
DeepSleep	GP Timers, RTC Timer, UART, I2C, WKUP GPIO, I/O Daisy Chain
MCU Only	DeepSleep wakeup events, Any MCU channel interrupt event
Standby	Any SoC interrupt event

Copyright © 2024 Texas Instruments Incorporated

6.2.4.8 USB Wakeup Scenarios

Table 6-8 summarizes different USB wakeup use cases which are supported in each system sleep state (DeepSleep, MCU-only or Standby). Three use case scenarios exist:

- **USB Connect**: Wakeup is cause by physically inserting the USB cable.
- **USB Disconnect**: Wakeup is caused by physically removing the USB cable.
- **USB Resume/Remote Wakeup**: Wakeup is caused by a USB resume or remote wakeup. For example, a USB mouse click can cause a USB remote wakeup.

Within each wakeup use case, each row describes whether or not that type of wakeup is supported in each system sleep mode. USB mode (host or device) is also considered.

There are three possible Wakeup events that are generated:

- **PHY Signal WKUP**: this is an internal wakeup signal to the wakeup processor that is generated by the USB PHY based off of USB signaling.
- **PHY VBUS WKUP**: this is an internal wakeup signal to the wakeup processor that is generated by the USB PHY based off of a level change on VBUS voltage. Ensure you level shift the voltage to conform to the I/O requirements. When VBUS transitions from 0V to 5V (or vice versa), the transition will trigger a wakeup.
- **ID Status WKUP**: this is a wakeup signal generated by a status change on the USB ID pin.

Table 6-8. USB Wakeup Use Cases Supported in System Sleep States

No.	USB Wakeup Use Case	System Sleep State	USB Controller State	USB Mode	Supported	USB Wakeup Event
1	USB Connect	DS/MCU-only/ Standby	Clock Gated Register Contexts Retained	Host	Yes	PHY Signal WKUP
2		DS/MCU-only/ Standby	Clock Gated Register Contexts Retained	Device	Yes	PHY VBUS WKUP
3		DS/MCU-only/ Standby	Clock Gated Register Contexts Retained	Undetermined	Yes	ID Status WKUP
4	USB Resume / Remote Wakeup	DS/MCU-only/ Standby	Clock Gated Register Contexts Retained	Host	Yes	PHY Signal WKUP
5		DS/MCU-only/ Standby	Clock Gated Register Contexts Retained	Device	Yes	PHY Signal WKUP
6	USB Disconnect	DS/MCU-only/ Standby	Clock Gated Register Contexts Retained	Host	Yes	PHY Signal WKUP, ID Status WKUP
7		DS/MCU-only/ Standby	Clock Gated Register Contexts Retained	Device	Yes	PHY VBUS WKUP

6.2.4.9 Main Oscillator Control During DeepSleep

The DeepSleep oscillator circuit is used to control the main oscillator by disabling it during deep sleep and enabling during active/wakeup. By default, during reset, the oscillator is enabled and the oscillator control circuit comes up disabled (in-active). In order to activate the oscillator control circuit for DeepSleep, a register must be programmed. Once this is set and whenever the Device Manager enters DeepSleep, the oscillator control will disable the oscillator causing the clock to be shut OFF. Any event from the wakeup sources will cause the oscillator control to re-enable the oscillator after a programmed period in a register.

Copyright © 2024 Texas Instruments Incorporated

The Device Manager will always be powered up. But when the main oscillator is in power down / OFF state, the Device Manager will not receive any clock.

6.2.4.10 Low Power Mode Sequencing with Device Manager

The device contains a Device Manager (DM) to handle all of the low-level power management control of the device including the Low Power Mode transitions. It is part of the DM Always ON (AON) power domain as shown in Figure 6-5. A firmware is provided by Texas Instruments that includes all of the necessary functions to achieve low power modes. Inter-Processor Communication (IPC) registers are available to communicate with the Device Manager so the user can provide certain configuration parameters based on the level of low power that is required.

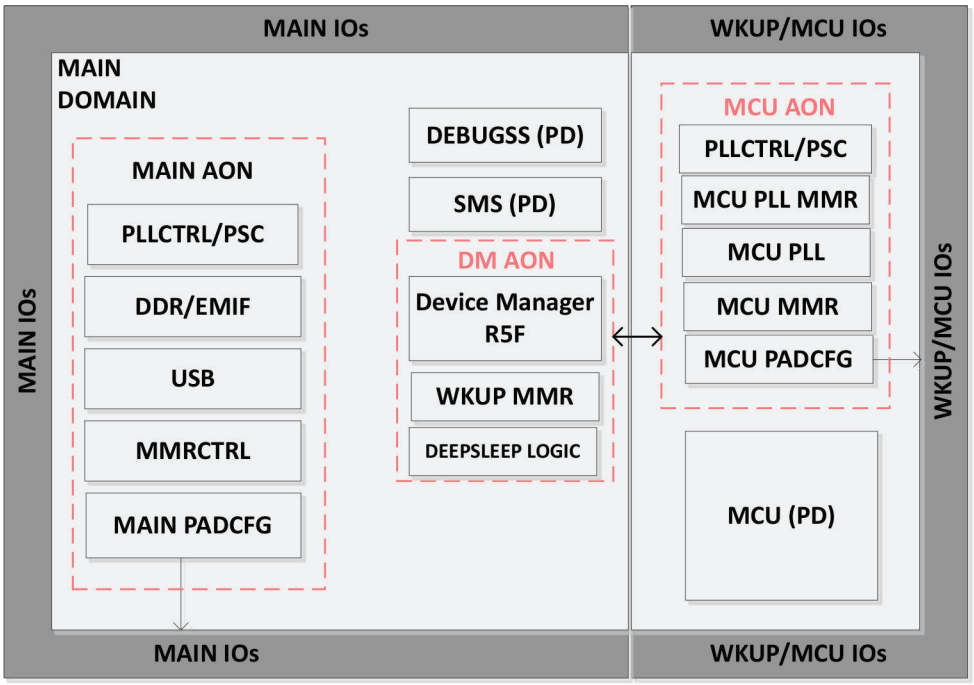

Figure 6-5. Key SoC Components for Low Power Modes

The followings are prerequisites to start a low power mode sequence.

- All IO Pad config MMRs configured appropriately for a target low power mode
- Save device configuration / context information to external DDR
- Power initiator, likely A53 running RTOS or Linux or MCU M4 running RTOS, is responsible for putting other application cores in proper state (OFF) and restarts after resume.
- Power initiator core will signal for DM sleep sequence to begin.
- Application software is responsible for DS padconf configuration for all states needed in low power mode.
- Secure Stub must be signed and encrypted as a bootable image and loaded to SPS region by HLOS or bootloader
- DM Stub must be loaded to NSPS region by HLOS or bootloader
- TISCI_MSG_PREPARE_SLEEP comes from PM initiator (Secure or Non-secure)
  - Contains Desired State to Enter (DeepSleep, MCU-Only, Standby)
  - Flags that can be used to set HALT points for debug
  - Memory address to be used for TIFS context encrypt and save. If bad address is given on resume, decrypt will fail.
- TISCI_MSG_ENTER_SLEEP message must contain resume address of cores to be restarted by firmware
- WKUP_CTRL.PMCTRL_SYS.lpm_en should be configured to let DeepSleep Logic control PMIC_LPM_EN output before sequence.

Sleep Sequencing

Copyright © 2024 Texas Instruments Incorporated

1. During Active power mode, the MPU sends TISCI_MSG_PREPARE_SLEEP with DeepSleep selected to the DM and TISCI_MSG_ENTER_SLEEP with resume address to the TIFS core.
2. TIFS Core prepares for DeepSleep and messages HSM core to tell it to enter WFI
3. HSM Core prepares for DeepSleep and enters WFI
4. TIFS Core sends TISCI to DM for suspend finish and enters WFI.
5. DM waits for all cores to enter WFI, timeout and abort if they do not.
6. DM executes DM Stub sequence, place DDR into Self Refresh, configures selected wakeup sources and HFOSC clock and PD.
7. DM enters in WFI
8. DS HW Logic gates off HFOSC0 and Powers-off
9. DS state is captured in MMR.
10. Device in DS state

Wakeup Sequencing

1. Event of IO daisy chain or internal Timer/RTC events generates async wake-up event
2. This async wake-up event turns on high frequency oscillator (HFOSC)
3. DM exists WFI as soon as HFOSC clock is available.
4. DM detects that it is resuming from Deep sleep mode
5. DM goes through wake-up sequence: enabling MCU PLL etc
6. DM Powers-on MCU, SMS, DEBUGSS
7. DM configures DS_MAIN_POR_PDOFF register to deassert MCU PORz and Main PD Domains (SMS, DEBUGSS, MAINIP)
8. Wait for RESETSTATz indication to determine Main is out of Reset
9. TIFS Boots-up -it detects that it is resuming from DeepSleep state
10. DM and TIFS handshake to start the device restore
11. Decrypts Secure Stub from DM Secure RAM and Messages DM on completion
12. DM configures Main Domain PLLs
13. DM programs Main PSC to enable clocks to Main components (DDR, USB, Peripherals)
14. DM checks PSC to ensure DDR and USB are enabled and resets are de-asserted.
15. DM configures DDR to restore to the state it was prior to entering sleep mode
16. DM enables A53 –enables PLLs, programs Reset Vector, etc...
17. A53 reads context data from external DDR and restores MAIN/WKUP/MCU configuration including IO pads etc
18. Device enters normal mode of operation

Note

Low Power Mode sequencing is controlled via Device Manager. For more information how to use Device Manager, see TISCI API available at ti.com.

6.2.4.11 I/O Power Management and Daisy Chaining

I/O power management is useful when the main oscillator is clock gated and the power domains for the peripherals connected to LVCMOS I/Os are OFF (power-gated state) in DeepSleep or MCU-Only. Since the I/Os are controlled by modules in power-gated state, I/O power management is required to have flexibility when interfacing with external devices. During DeepSleep or MCU-Only, the wakeup feature is active, described in **Wakeup** below. Isolation is required to be activated and deactivated during sleep and wakeup sequencing, respectively (see following description of **Isolation**).

Copyright © 2024 Texas Instruments Incorporated

Three aspects comprise I/O cell power management:

- **Isolation** - Isolation from power state transitions.
  - When ISOLATED, the I/Os will hold their previous state (0,1, tristate) until the ISOLATION is released. The controls for the ISOLATION travel through the chain. Isolation is controlled during sleep and wakeup sequencing.

Note

The Device Manager must have the optional feature to remove isolation from DDR I/Os while allowing rest of the I/O isolation to be removed later. This allows for software to restore any critical peripherals from DDR and ensure the peripheral is in a required or valid state (like GPIO) before the remaining I/Os are removed from Isolation.

- **Wakeup** - I/O PAD can be individually enabled for wakeup using PADCONFx.wkup_en register bit.
  - The wakeup controls and events (as well as enable and disable controls) travels through asynchronously through the chain during DeepSleep or MCU-Only. The global wakeup chain is enabled/controlled by the Device Manager. This is global control is achieved by qualifying each of the I/O PAD wakeup enables with global wakeup daisy chain control coming from Device Manager.
- **PADCONFIG** - Individual control on what will be the IO state during Isolation using PADCONFIGx control register bits.
  - The PADCONFIG registers must be used only if the default state of the I/O during the low power state does not meet system requirements.

The following terminal signal names are unique and are excluded from the isolation and wakeup daisy chains. Control of these signals can remain with GPIO even when I/O isolation is enabled. Refer to the device datasheet to determine which pins map to each signal name. Each pin has a corresponding GPIO that can be mapped to one of the GPIOs in the GPIO module.

- System signals: MCU_RESETSTATz, WKUP_CLKOUT0, EXT_REFCLK1
- OLDI0 interface: All OLDI0_x signals

The following terminal signal names are excluded from the isolation and wakeup daisy chains and not muxed with GPIO signals. Hence, these signals cannot be used as a wakeup event.

- System signals: MCU_RESETz, MCU_PORz, MCU_ERRORn, WKUP_CLKOUT0, EXT_REFCLK1, RESET_REQz, RESETSTATz, PORz_OUT
- JTAG interface: TMS, TDI, TDO, TCK, TRSTn, EMU0, EMU1
- Oscillator signals: MCU_OSC0_XO, MCU_OSC0_XI, WKUP_LFOSC0_XO, WKUP_LFOSC0_XI
- CSI0 interface: All CSI0_x signals
- USB signals: USB0_DP, USB0_DM, USB0_RCALIB, USB0_VBUS, USB1_DP, USB1_DM, USB1_RCALIB, USB1_VBUS
- DDR interface: All DDR0_x signals

6.2.5 Power Supply Modules

6.2.5.1 Power OK (POK) Modules

Note

All POK modules are in MCU domain regardless of the domain of the voltage they monitor.

Note

In this family of devices, the Power-on-reset module is used only for voltage monitoring, as three additional POK modules. For more information about POK functionality in POR module - voltage being monitored and type (under voltage or over voltage), see Section 6.2.5.2.

Copyright © 2024 Texas Instruments Incorporated

POK modules are responsible for accurately detecting the voltage levels. Each module is trimmed to account for process and temperature variations. The trim values are provided by eFuse chains enabled by a POR/Reset Generator (PRG) module.

Two types of POK modules are implemented in this family of devices - POK and POK_SA. See Table 6-9 about the type of a POK and the voltage it is monitoring. More information about the two types of POKs is given further in this section.

Table 6-9. POK Module Overview

POK Module Instance Name	PRG Index (3)	POK Index (1)	Voltage Monitored	Module Type	OV/ UV(2)	Description
IPOK_VDD_CORE_OV	PRG0	4	VDD_CORE	POK_CORE	OV	Voltage Monitor for VDD_CORE
IPOK_VDDA_PMIC_IN_UV	PRG0	3	VMON_VSYS	POK_SA	UV	Voltage Monitor for PMIC_IN
IPOK_VDDS_DDRIO	PRG1	4	VDDS_DDR	POK_CORE	UV/OV	Voltage Monitors for DDRIO
IPOK_VDDR_CORE	PRG1	3	VDDR_CORE	POK_CORE	UV/OV	Voltage Monitors for VDDR_CORE
IPOK_VMON_CAP_MCU_GENERAL	PRG1	2	CAP_VDDS_MCU	POK_CORE	UV/OV	Voltage Monitors for MCU mid-rail
IPOK_VDDSHV_MAIN_1P8	PRG1	1	VMON_1P8_SOC	POK_1P8	UV/OV	Voltage Monitors for 1.8-V I/O supply in MCU
IPOK_VDDSHV_MAIN_3P3	PRG1	0	VMON_3P3_SOC	POK_3P3	UV/OV	Voltage Monitors for 3.3-V I/O supply in MCU

(1) The POK Index also represents the mapping index for relevant under and overvoltage status and interrupts where applicable.
(2) UV: POK is set for undervoltage detection. OV: POK is set for overvoltage detection. UV/OV: POK monitors both OV and UV through a Ping-Pong mechanism.
(3) Ping-pong mechanism is only applicable to PRG1.

Figure 6-6 and Figure 6-7 represent the block diagrams of the two POK types.

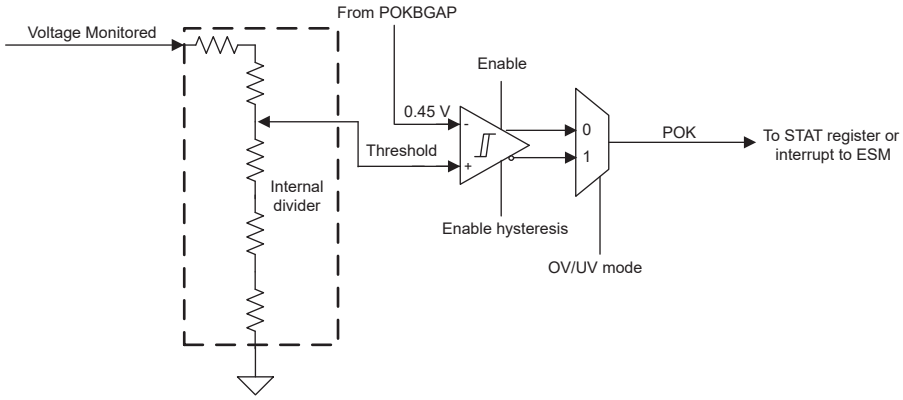

Figure 6-6. POK Block Diagram

Copyright © 2024 Texas Instruments Incorporated

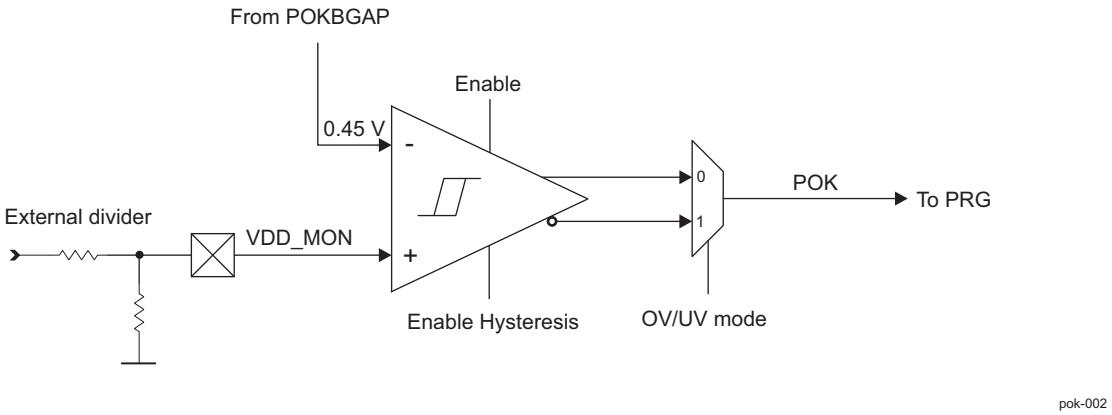

Figure 6-7. POK_SA Block Diagram

Vref for both POK and POK_SA types in Figure 6-6 and Figure 6-7 is supplied from POK module, see Section 6.2.5.2

6.2.5.1.1 Configuration Registers

Configuration registers needed for POK (Supervisor Module) are given in *POK Configuration Registers*. For each POK there is one comparator that is controlled through the registers. These registers decide the functionality of the POK Comparator. It decides if it is UD/OD mode and also the threshold voltages. In the current implementation only SET_THRESHOLD[8:1] bits are used.

Comparator threshold levels and corresponding configuration register settings are given in the following tables:

- POK_CORE: Table 6-11
- POK_1P8: Table 6-12
- POK_3P3: Table 6-13

Table 6-10. POK Configuration Registers

Register Name	POK Type
MCU_CTRL_MMR0_POK_VDD_CORE_OV_CTRL[7:0]	POK_CORE
MCU_CTRL_MMR0_POK_VDDR_CORE_UV_CTRL[7:0]	POK_CORE
MCU_CTRL_MMR0_POK_VDDR_CORE_OV_CTRL[7:0]	POK_CORE

6.2.5.2 Power on Reset (POR) Module

This section describes the Power on Reset (POR) module.

6.2.5.2.1 POR Overview

POR module in this family of devices is responsible for detecting proper operating voltage levels on VDDA_MCU (under voltage), and both under and over voltages for analog supply in MCU domain.

Table 6-14 shows POR modules allocation within device domains.

Table 6-14. POR Modules Allocation within Device Domains

Module Instance	Domain	
	MCU	MAIN
POR0	✓	-

6.2.5.2.2 POR Integration

The device supports one instance of a Power on Reset (POR) module - MCU_POR0. MCU_POR0 is located in MCU domain. Figure 6-8 shows the integration of MCU_POR0.

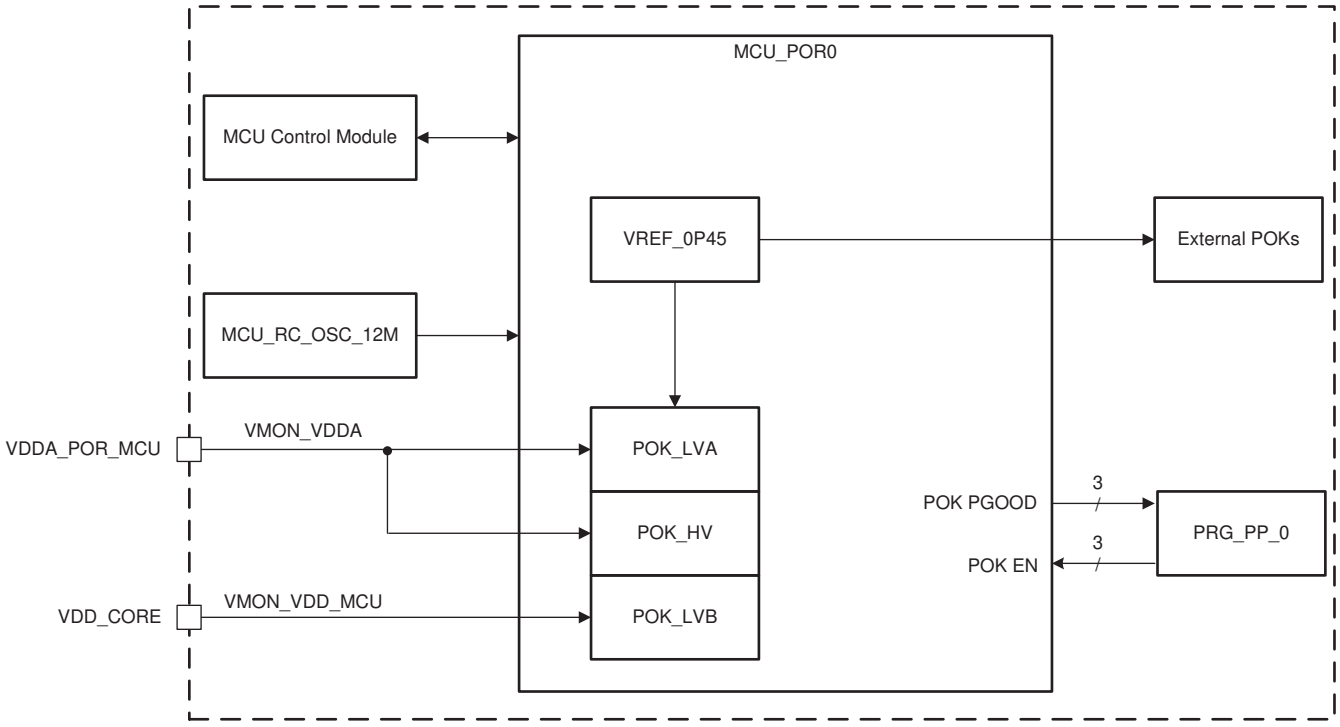

Figure 6-8. POR Integration

Copyright © 2024 Texas Instruments Incorporated

Table 6-15. POR Modules

POR Module Instance Name	PRG Index	POK Index	Voltage Monitored	Module Type	OV/ UV(1)	Description
POKHV	PRG0	2	VDDA_MCU 1.8 V	POR	UV	Internal POR generation and power monitoring for 1.8-V supply and VDD_CORE
POKLVA	PRG0	1	VDDA_MCU 1.8 V	POR	OV	Internal POR generation and power monitoring for 1.8-V supply and VDD_CORE
POKLVB	PRG0	0	VDD_CORE	POR	UV	Internal POR generation and power monitoring for 1.8-V supply and VDD_CORE

(1) UV: POK is set for under voltage detection. OV: POK is set for over voltage detection. UV/OV: POK monitors both OV and UV via Ping-Pong mechanism.

6.2.5.3 PoR/Reset Generator (PRG) Modules

This device has two PoR/Reset Generator (PRG) modules – PRG_PP_0 and PRG_PP_1. Both of these modules are located in the MCU domain.

6.2.5.3.1 PRG Overview

A PRG module is responsible for implementing enable/disable controls and event/interrupt masking logic on all POK outputs.

Figure 6-9 shows the PRG module overview.

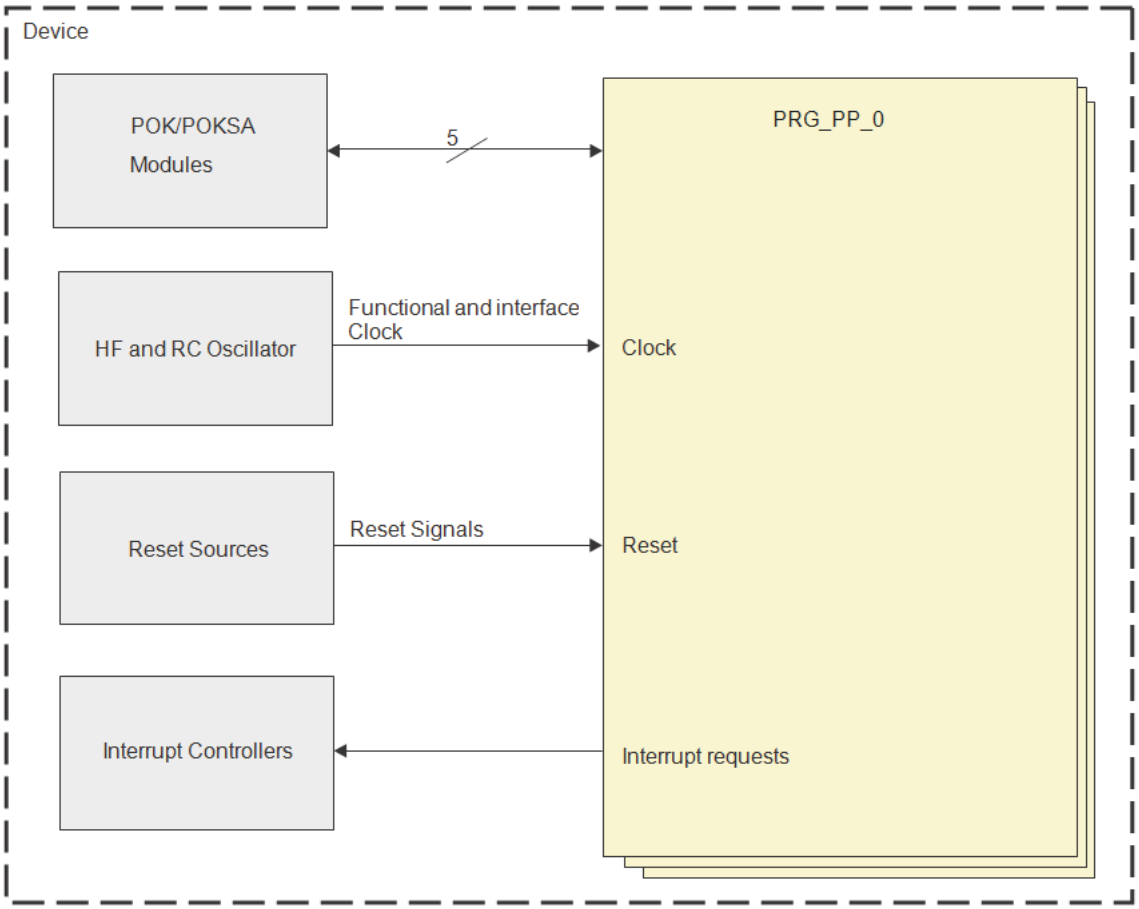

Figure 6-9. PRG0 Overview

Figure 6-10 shows the PRG module overview.

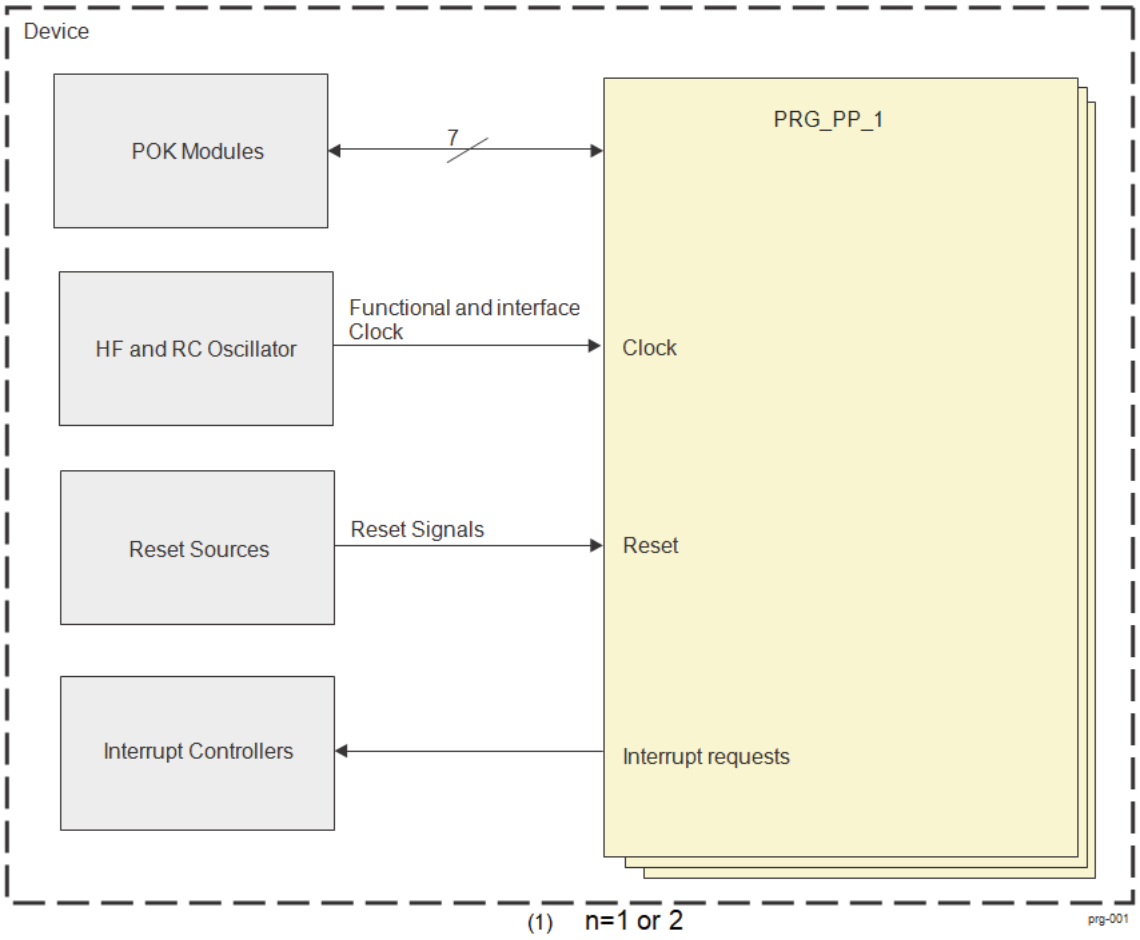

Figure 6-10. PRG1 Overview

6.2.5.4 Power Glitch Detect (PGD) Modules

A Power Glitch Detect (PGD) circuit is used to detect short duration “glitches” on the core and MPU power supplies. The PGD provides a low output when no glitch is detected and a high output when a glitch is detected.

Table 6-16 shows PGD modules allocation within device domains.

Table 6-16. PGD Allocation within Device Domains

Module Instance	Domain		
	WKUP	MCU	MAIN
IPGD_VDD_CORE	-	✓	-

Figure 6-11 shows the PGD block diagram.

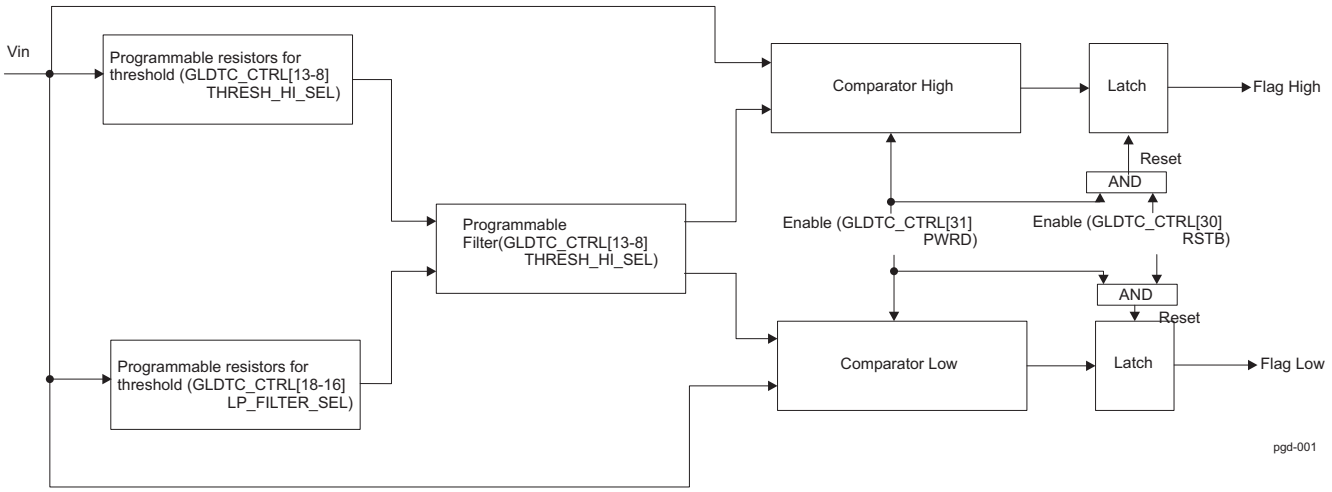

Figure 6-11. PGD Block Diagram

Table 6-17 Summarizes the PGD integration.

Table 6-17. PGD Integration Summary

Module Instance	Monitored Voltage	PGD Control/Status Registers(1)
IPGD_VDD_CORE	VDD_CORE	

(1) For more information about control registers, see , *Control Module (CTRL_MMR)*.

Note

A flag status bit in corresponding STAT register is cleared by clearing the [30] RSTB bit in the corresponding CTRL register, see for STAT and CTRL registers for a certain PGD module.

Note

For more information on the interconnects, see , *System Interconnect*.

For more information on the power, reset and clock management, see the corresponding sections within , *Device Configuration*.

For more information on the device interrupt controllers, see , *Interrupt Controllers*.

6.2.5.5 Voltage and Thermal Manager (VTM)

6.2.5.5.1 VTM Overview

This section describes the Voltage and Thermal Manager (VTM) module in the device.

The VTM module supports voltage and thermal management of the device by providing control of on-chip temperature sensors.

The device supports a single VTM module, VTM0, which is located in the WKUP domain. VTM0 has two associated temperature monitors, Temp_Sensor_Main_0, and Temp_Sensor_Main_1, each of which are located near hotspots in the device die.

Figure 6-12 shows VTM module allocation within device domains.

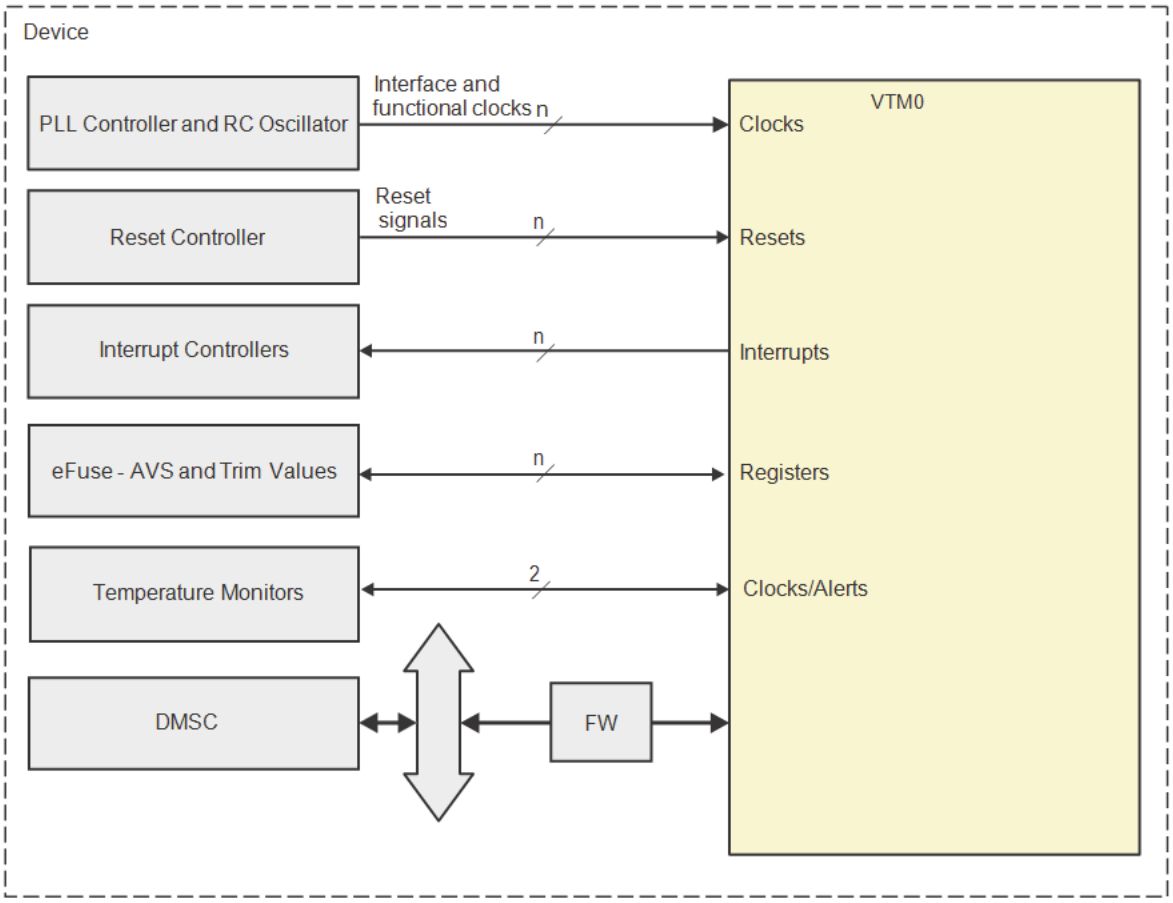

Figure 6-12. VTM Overview

6.2.5.5.1.1 VTM Features

VTM module supports the following features:

- Programming of temperature-crossing thresholds
- Signals when programed thresholds are exceeded - up to 3 alerts:
  - Three full reference 10-bit temperature threshold points, THPT1, THPT2 and THPT0.
  - Two relative 4-bit delta values vs THPT1 (one an increment and another a decrement), each able to set additional threshold point, THPT2 and THPT0.
- Supports up to 8 temperature monitors
- Allows resolution of 0.5°C for temperature reading and threshold point temperature alert/interrupt generation.
- Supports PMIC/LDO set-up with Class-0 VDD-VID settings
- Support of tentative customization of OPP voltage per device (in support of multiple OPPs)

Copyright © 2024 Texas Instruments Incorporated

- AVS-voltage or thermal management for up to 8 voltage domains
- Maximum temperature alert
- Supports one shot sampling mode and continuous monitoring mode for the sensors
- Contains registers with reset defaults from e-fuse values needed to supports SR-Class0 via e-fuse/ manufacturing calibration and firmware and/or software using those values to program the PMIC/LDO with the Class-0 VDD-VID setting.
- Contains registers with reset defaults from e-fuse values per SOC for a tentative customization of OPP voltage per device (in support of multiple OPPs/DVFS).
- Supports a group of registers for up to 8 core voltage domains that require AVS-voltage management or thermal management in a contiguous memory region to support access privilege control by Firewall within its address space.
- Core voltage domains that don't require any SR-Class0 or thermal management shall not be controlled or map to any of the MCU_VTM0 voltage domain group.
- Contains registers with reset defaults from e-fuse values or TIE-OFFs to provide control for temperature monitors and interrupt generation needed to support thermal management customized if necessary in a per voltage domain basis.
- Provides register control, status and interrupt generation, and alerts for up to 8 temperature monitors.
- Stores in the registers the defaults for temperature detection threshold points and other temperature monitor control values for Firmware usage.
- Samples, captures, and allows for register read of the on-die temperature monitor present reading.
- Provides interrupt and status for out of range temperature reading.
- Provides one full reference 10-bit temperature threshold point, THPT1.
- Provides 2 relative 3-bit delta values versus THPT1, one an increment and another a decrement, which yields 2 additional threshold points, THPT2 and THPT0, in close proximity to THPT1.
- Provides 3 temperature threshold point alert signals (level), GT_TH1_ALERT, GT_TH2_ALERT and LT_TH0_ALERT, for each one of the up to 8 temperature monitors.
- Provides 3 temperature threshold point interrupt flags, GT_TH1_INT, GT_TH2_INT and LT_TH0_INT, for each one of the up to 8 voltage domains.
- Provides 3 temperature threshold point interrupts (level-only) for the entire MCU_VTM0, GT_TH1_INT, GT_TH2_INT and LT_TH0_INT, which are driven out of MCU_VTM0 and are shared by the 8 voltage domains. The output port interrupts correspond to the OR function of the contributions of the 8 voltage domains.
- Software must read the corresponding flags in each of the 8 voltage domains to identify which voltage domain is active.
- Allows for temperature reading and threshold point temperature alert and interrupt generation with 0.5°C of resolution.

Note

The VTM in this family of devices implements two temperature monitors.

6.2.5.5.1.2 VTM Not Supported Features

- No support for AVS-Class0 with temperature compensation (AVS0 + TC)
- No support internal to MCU_VTM0 for any AVS Class technology other than Class0
- No support for K1 or K2 4/6-bit VCNTL/VID parallel or 2-step interfaces.
- No integrated I2C inside VTM
- No direct hardware triggering of I2C transactions by VTM. Only interrupt and event generation is supported.
- No support for voltage and thermal management of I/O voltage domains. Only core domain voltage/thermal management is supported.
- VTM0 does not contain or support register groups or control hooks for I/O voltage domains.
- Core voltage domains that do not require any voltage or thermal management are not controlled or mapped to any of the VTM0 voltage domain groups.
- Everything else not explicitly listed in Section 6.2.5.5.1.1 is not supported.
- No oversampling of the temperature reading
- No support for eFuse defaults of all register values

Copyright © 2024 Texas Instruments Incorporated

6.2.5.5.2 VTM Functional Description

6.2.5.5.2.1 VTM Temperature Status and Thermal Management

VTM module provides temperature reading and interrupt/alert information for thermal management.

Note

VTM functions are controlled through the DMSC. For more information how to use DMSC, see the TISCI API .

VTM controls the temperature monitors in the die. A single VTM can control up to 8 monitors via its registers. The VTM enables the sensors periodically to keep the reported data continually updated becuase the device sensors are not periodical. The temperature value coming back from the monitor is captured and reported by the VTM registers. The VTM keeps the sensors in reset state when not enabled to save power and reduce sensor usage to maximize the sensor life.

Note

A temperature diode sensor is used to measure silicon junction temperature, for more information about temperature diode, see the device-specific Datasheet.

6.2.5.5.2.1.1 10-bit Temperature Values Versus Temperature

Table 6-18 shows a table lookup method for translating code to temperature from temperature monitors which correspond to the temperature measured read from the VTM0_VTM_TMPSENS_STAT_J [9-0] DATA_OUT bitfields. Table 6-18 also provides the values for the temperatures coded in VTM0_VTM_MISC_CTRL2 [25-16] MAXT_OUTRG_ALERT_THR0 and VTM0_VTM_MISC_CTRL2 [9-0] MAXT_OUTRG_ALERT_THR thresholds.

Table 6-18. Temperature Translation Table

Parameter Type	Value								
Temperature [°C] (rounded)	-40	-25	0	25	50	75	100	125	150
Temperature [°C] (unrounded)	-40.03	-24.95	0.01	25.02	49.94	75.03	100.02	124.97	150.00
DATA_OUT Code	28	77	164	260	366	485	620	773	949

Table 6-19 shows a table that gives coefficients of polynomial to calculate code or temperature. The equation to calculate code or temperature is:

$y = a4 \times x^4 + a3 \times x^3 + a2 \times x^2 + a1 \times x + a0$

Table 6-19. Equation Method to Calculate Code or Temperature

Function	Unit	Coefficient				
		a4	a3	a2	a1	a0
Code = f(Temperature)	Decimal value of code	4.9847E-08	1.6972E-05	6.8759E-03	3.6509E+00	1.6407E+02
Temperature = f(Code)	°C	-9.2627E-12	6.0373E-08	-1.7058E-04	3.2512E-01	-4.9002E+01

6.3 Reset

This chapter describes the device reset signals and contains details on reset management.

6.3.1 Overview

Reset Introduction

A reset is designed to bring a device or subsystem into a known state. Resets occur after power up events, as well as through software and hardware reset requests. This section introduces the device reset capabilities and functionality.

Device Resets

The Device Power-on-Reset (POR) is controlled by the external pin MCU_PORz. This pin is driven by an external (off-chip) "Power-Good" Circuit or Power Management IC (PMIC). The MCU_PORz pin should be held active LOW (0) during the entire power-up phase. The device should be held in reset until all power supplies are stable with an additional delay for the High Frequency Oscillator (HFOSC0) clock to stabilize.

The SoC is divided into two separate functional Reset Domains: MCU Reset Domain and MAIN Reset Domain (each containing specific processing cores and peripherals).

- MCU Reset Domain: Managed by the MCU Domain, PLLCTRL and PSC, this includes ARM® Cortex®- M4F MCU Processor (M4FSS).
- MAIN Reset Domain: Managed by the MAIN Domain, PLLCTRL and PSC, this includes the high performance application Arm Cortex-A53 cores (A53SS), Device Management and Low Power Management (DM R5F), Security Controller (SMS0 - Dual core M4F) and Programmable Real-Time Unit Subsystem (PRUSS0).
- A subset of MAIN and MCU domains is logically grouped ad WKUP domain. This domain is always on and is responsible for device low power management. DM R5F is located in this domain. See Figure 6-15.
- Security controller SMS has 2 submodules:
  - TIFS (TI Foundational Security) has a dedicated M4F responsible for device security
  - HSM (Hardware Security Mode) has a dedicated M4F responsible for customer/application centric security (such as AutoSAR)

Figure 6-13 illustrates the high-level reset domain partition.

6.3.1.1 MCU Domain Supported Resets

- Power-On-Resets
  - MCU_PORx device pin: This power-on-reset will reset the entire device including MCU and MAIN domains.
- Warm Resets
  - MCU_RESETz device pin
  - MCU domain software warm reset
  - MCU domain ESM error reset
  - SMS cold reset

  The warm resets listed above will reset the entire device including MCU and MAIN domains.
- Local Module Resets
  - MCU domain LPSC module local reset: This reset is generated by the MCU PSC to locally reset the M4F CPU core

6.3.1.2 MAIN Domain Supported Resets

- Power-On-Resets
  - MAIN domain software POR reset
  - MAIN domain hardware POR reset generated by MCU_PORz
- Warm Resets
  - RESETz_REQ device pin
  - MAIN domain ESM error reset
  - MAIN domain software warm reset
  - SMS cold reset
  - MCU domain warm reset will also generate a MAIN domain warm reset
- Local Module Resets
  - MAIN domain LPSC module local reset: This reset is generated by the MAIN PSC to locally reset the Processor cores (A53, SMS M4F, DM R5F, PRUSS)

The device can be configured via software such that a Main domain resets can be isolated from MCU domain. When the MCU domain is configured for reset isolation, MAIN domain resets will only reset the MAIN domain and the MCU domain will remain unaffected by all MAIN domain resets. All MCU domain resets will cause a reset to the entire device (including MAIN and MCU domains).

6.3.3 Reset Status

Reset Status shows the Reset Status functionality. An output pin or software bit is used to represent the status of a specific individual reset.

Table 6-21. Reset Status

Reset Status Name	Reset Status Source	Reset Status Info	Signal Active Level	Reset Signal Details
MCU CTRLMMRStatus Register	Register	4 bits in CTRLMMR on MCU warm reset status and assertion.	Status bits read active HIGH (1) when a particular reset is asserted.	
WKUP CTRLMMR Status Register	Register	4 bits in CTRLMMR on WKUP warm reset status and assertion.	Status bits read active HIGH (1) when a particular reset is asserted.	
PORz_OUTz	Output Pin	On/Off pin status of MAIN PORz reset	Active LOW (0)	MAIN_PORz_OUT Status Pin
RESETSTATz	Output Pin	On/Off pin status of MAIN warm reset	Active LOW (0)	MAIN_RESETSTATz Status Pin
MCU_RESETSTATz	Output Pin	On/Off pin status of MCU PORz reset	Active LOW (0)	MCU_RESETSTATz Status Pin
MCU_ERRORn	Output Pin	On/Off pin status of MCU ESM_ERROR reset	Active LOW (0)	MCU_SAFETY_ERRORn Status Pin

Copyright © 2024 Texas Instruments Incorporated

6.3.3.1 Reset Source Status Registers

All warm reset sources which trigger a device/domain warm reset are captured in the MCU domain CTRLMMR reset status register **CTRLMMR_MCU_RST_SRC**. This register is only reset on MCU_PORz.

The MCU domain CTRLMMR **CTRLMMR_MCU_RST_SRC** register is shadowed in MAIN domain CTRLMMR **CTRLMMR_RST_SRC** so that MAIN domain processors can read it without directly accessing the MCU domain CTRLMMR.

After recovery from warm reset, software can read the CTRLMMR reset source register **CTRLMMR_RST_SRC** to identify the source of previous reset. After reading this reset source register, software must clear the register.

Reset status bits read active HIGH (1) when a particular reset is triggered.

The following reset sources, which cause MCU and MAIN domain resets, are captured in the MCU domain CTRLMMR reset source register:

- MCU_RESETz (Reset by Hardware Pin)
- SW_MCU_WARMRSTz (Reset by MCU domain CTRLMMR[1])
- SW_MAIN_PORz_MCUMMR (Reset by MCU domain CTRLMMR[1])
- SW_MAIN_PORz_MAINMMR (Reset by MAIN domain CTRLMMR[1])
- MAIN_RESET_REQz (Reset by Hardware Pin)
- SW_MAIN_WARMRSTz_MCUMMR (Reset by MCU domain CTRLMMR[1])
- SW_MAIN_WARMRSTz_MAINMMR (Reset by MAIN domain CTRLMMR[1])
- SMS_COLD_OUT_RST_n (Reset by SMS)
- SMS_WARM_OUT_RST_n (Reset by SMS)
- THERM_MAXTEMP_OUTRANGE_ALERT (Reset by VTM Max Temperature Alert)
- SYSR_ASSERTRESET_n (Reset by DEBUGSS)
- ESM_ERROR_RST_n (Reset by ESM Error)
- DM_WDT RST_n (Reset by WKUP WDT Timeout during Deepsleep mode)
- DM_MAIN_PORz (Reset by DS_MAIN_POR_PDOFF a WKUP domain CTRLMMR[1] during deepsleep)
  - MCU ESM Error will reset entire device
  - MAIN ESM Error will only reset MAIN domain when MCU domain is isolated. When MCU domain is not isolated, it will warm reset both MCU and MAIN domains.

Note

1. MAIN domain software WARMRSTz and PORz control registers are defined in both WKUP domain CTRLMMR and MCU domain CTRLMMR.

When the MCU domain is isolated from MAIN domain, MCU M4FSS processor can reset the MAINdomain, by programming the reset control registers defined in the MCU domain CTRLMMR. This way MCU M4FSS does not need to access MAIN domain CTRLMMR for MAIN domain reset action.

Whena MAIN domain processor (A53, SMS, R5F) needs to issue resets to MAIN domain on error detection they will use the WARMRESETz and PORz MMR bits defined in the WKUP domain CTRLMMR.

6.3.3.2 MCU_RESETSTATz Status Pin

The MCU_RESETSTATz pin indicates the internal reset status of the device (active LOW). When LOW, it indicates that the MCU and MAIN domains are in warm reset state. When HIGH, it indicates that the MCU is out of warm reset state. Refer to Section 6.3.3.4 for MAIN domain reset status.

6.3.3.3 MCU_ERRORn Status Pin

The MCU_ERRORn pin indicates the MCU domain ESM status. This Output is used to signal an external agent that it needs to (or may need to) intervene because of an error. The Error Pin Output is active Low or PWM,

Copyright © 2024 Texas Instruments Incorporated

based on the ESM Error Pin Control register pwm_en field (Refer ESM IP) . This pwm_en field should only be modified when the ESM is disabled, based on the Global Enable register. Refer ESM chapter for details.

While in Power-On-Reset, the Error Pin is active (asserted low). SoC drives a Low via a weak internal pull-down. After Power-On-Reset condition is removed, ESM will drive the Error Pin. During a Warm Reset the state of the Error Pin is unchanged (i.e. the Error Pin logic is only reset by asserting MCU_PORz low).

When MCU_ERRORn output pin is configured to operate in level mode, a LOW indicates the MCU ESM module has registered an error. A HIGH indicates that there are no MCU ESM errors.

When MCU_ERRORn output pin is configured to operate in PWM mode, no error is indicated by continuous toggle according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external device (such as a PMIC) that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods should be programmed such that they fit within the expectation of the external device.

Note

This signal can be used by external safety devices to determine the device status and assert MCU_PORz if necessary.

6.3.3.4 RESETSTATz Status Pin

This pin indicates warm reset status (active LOW) of the MAIN domain.

When LOW, it indicates that the MAIN domain is in a warm reset state.

When HIGH, it indicates that the MAIN domain is out of reset.

The status of this signal will be captured in MCU CTRLMMR registers.

6.3.3.5 PORz_OUT Status Pin

This pin indicates the POR status of the MAIN domain (active LOW).

When LOW, it indicates the MAIN domain is in the POR state.

When HIGH, it indicates the MAIN domain is out of the POR state.

Note

PORz_OUT may be used to enable and/or disable output buffers of attached devices that share pins associated with BOOTMODE inputs, such that appropriate boot configuration values are allowed to propagate into the device without contention.

Copyright © 2024 Texas Instruments Incorporated

6.3.4 Reset Controls

The reset control registers enable, disable, and adjust specific reset operations. This section explains how to control certain device resets.

6.3.4.1 Reset Control Registers

MCU Domain Reset Control Registers shows the CTRLMMR registers that are able to enable and disable reset abilities and options.

Table 6-22. MCU Domain Reset Control Registers

Control Name	Control Action	Control Register
MCU_ESM_ERROR_RST_ENz	Enable MCU ESM_ERRORz reset	**CTRLMMR_MCU_RST_CTRL**
SMS_COLD_RESET_ENz	Enable SMS cold reset of MCU domain	**CTRLMMR_MCU_RST_CTRL**

Table 6-23. MAIN Domain Reset Control Registers

Control Name	Control Action	Control Register
MAIN_ESM_ERROR_RST_ENz	Enable MAIN ESM_ERRORz Reset	**CTRLMMR_RST_CTRL**
SMS_COLD_RESET_ENz	Enable SMS Cold Reset of MAIN Domain	**CTRLMMR_RST_CTRL**

Note

For more information, see *Control Module (CTRLMMR)*.

6.3.4.2 Reset Isolation

Reset Isolation Introduction

It is possible to isolate certain SoC modules and subsystems and prevent them from undergoing an arbitrarily generated warm reset. This is known as Reset Isolation. This section describes the device reset isolation capabilities.

Simple Reset Isolation Sequence Diagram shows a simple description of the device reset isolation sequence.

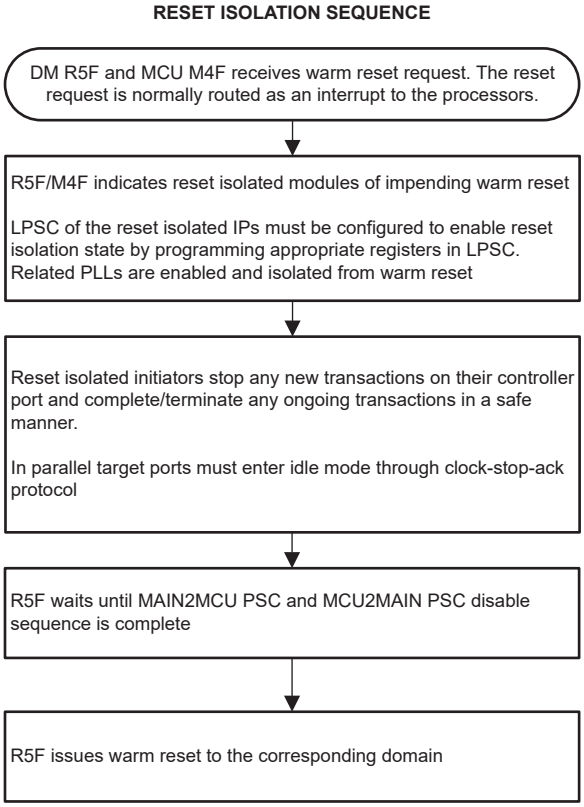

Figure 6-20. Simple Reset Isolation Sequence Diagram

MCU Reset Isolation Details

Detailed Reset Isolation Sequence Diagram shows a detailed description of the MCU reset isolation sequences.

6.3.5 Reset Details

Reset Details Introduction

The Reset Details section will break down the available device resets and explain operating details such as sequencing and reset logic diagrams. It also includes any additional information related to the device resets.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.1 POR Resets

6.3.5.1.1 SW_MAIN_PORz Reset

Reset Overview

This reset is a software controlled MAIN domain POR reset defined in **CTRLMMR_RST_CTRL** and **CTRLMMR_MCU_RST_CTRL**.

This software reset will generate a MAIN domain PORz.

M4FSS processor in MCU domain can trigger PORz to the MAIN domain by writing to the **CTRLMMR_MCU_RST_CTRL** register.

MAIN domain processors can reset the MAIN domain by writing to the **CTRLMMR_RST_CTRL** register.

When the MCU domain is configured as a safety domain it must be isolated from SW_MAIN_PORz.

A reset isolation sequence for the MCU domain must be complete prior to reset propagation.

CTRLMMR_RST_CTRL and **CTRLMMR_MCU_RST_CTRL** define a 4-bit field, SW_MAIN_POR[7:4], for generating a software-controlled POR for the MAIN domain (SW_MAIN_PORz).

When SW_MAIN_POR [7:4] field is set to “0110”, the MAIN domain is in POR reset state (SW_MAIN_PORz = LOW).

When SW_MAIN_POR [7:4] is set to any other value, the MAIN domain is out of POR reset state (SW_MAIN_PORz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

MCU Domain Effect

When MCU domain is configured as an independent domain, then the entire MCU domain is reset isolated. When MCU domain is not configured as independent domain then this SW_MAIN_PORz must not be used. Instead MCU_PORz pin functions should be used.

MCU IOs are not affected.

MAIN Domain Effect

All modules in MAIN domain are reset (including reset isolated modules).

IOs will enter safe state (as defined in the BALL STATE DURING RESET column of the Datasheet Pin Attributes table while this reset is active.

MAIN domain CTRLMMR boot configuration register is reset.

Device BOOTMODE pins will be re-latched after this reset is de-asserted.

Device will re-boot. During boot-up, R5FSS (secondary boot loader) will poll the CTRLMMR reset status and MCU ACTIVE MAGIC WORD registers and configure MCU domain/M4FSS processor accordingly.

Additional Details

PORz_OUT:

This pin indicates POR status output of the MAIN domain (active LOW).

When LOW, it indicates the MAIN domain is in POR state.

When HIGH, it indicates that the MAIN domain is out of POR state.

Copyright © 2024 Texas Instruments Incorporated

Note

PORz_OUT may be used to enable and/or disable output buffers of attached devices that share IOs associated with BOOTMODE inputs, such that appropriate boot configuration values are allowed to propagate into the device without contention

Note

The boot mode pins are latched internally on the rising edge of PORz_OUT and are reset isolated from all other device resets.

6.3.5.1.2 MCU_PORz Reset

Reset Overview

This is the POR reset signal (active LOW) for the entire device, controlled by the MCU_PORz HW Pin.

When LOW, it performs a POR reset on the entire device (MCU and MAIN domains) and puts IOs in a safe state (as defined in the BALL STATE DURING RESET column of the datasheet Pin Attributes table).

MCU Domain Effect

All modules in MCU domain are reset.

MCU IOs are in HHV state (Reset State).

When MCU_PORz is de-asserted, MCU IOs will enter the default state defined in the device Datasheet. MCU domain will be reconfigured by the device boot processor (secondary boot loader).

MAIN Domain Effect

All modules in the MAIN domain are reset.

MAIN domain IOs are in HHV state (as defined in the BALL STATE DURING RESET column of the datasheet Pin Attributes table).

When MCU_PORz is de-asserted, the MAIN domain IOs will enter default state as defined in the BALL STATE AFTER RESET column of the datasheet Pin Attributes table.

The device boot processor (secondary boot loader) will setup M4FSS as Safety or General-Purpose Processor.

6.3.5.2 Warm Resets

6.3.5.2.1 MAIN Domain Warm Reset Sequence Flow

MAIN Domain Warm Reset Sequence Flowchart explains the process for a typical MAIN domain warm reset.

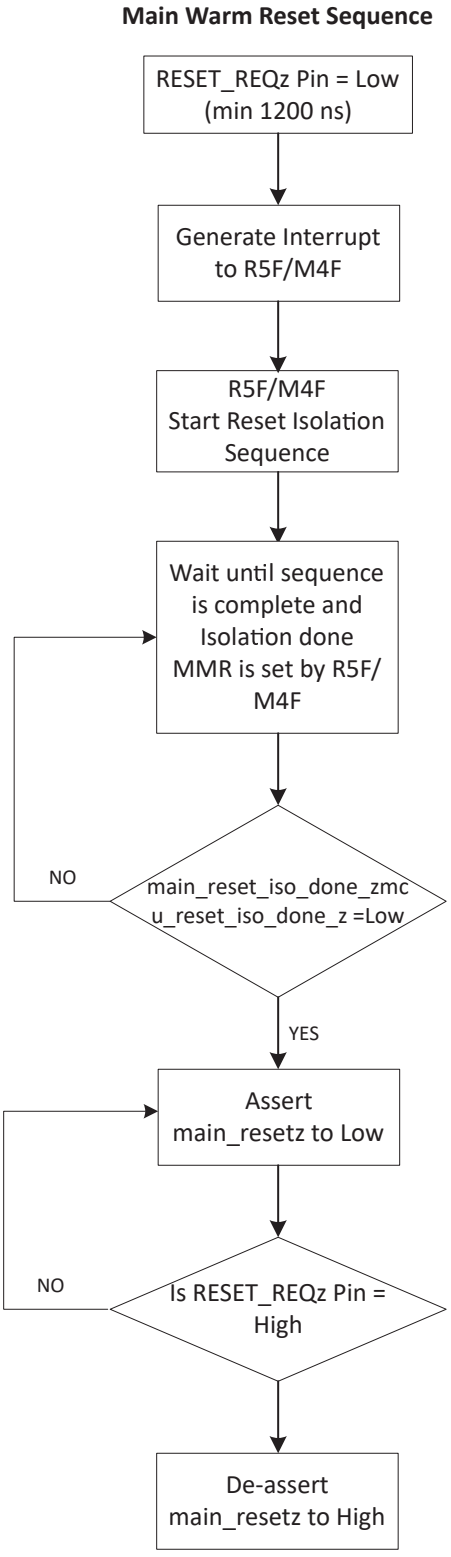

Figure 6-22. MAIN Domain Warm Reset Sequence Flowchart

Copyright © 2024 Texas Instruments Incorporated

6.3.5.2.2 MAIN_RESETz_REQ Reset

Reset Overview

This reset signal is the MAIN domain warm reset request (active LOW) controlled by the RESET_REQz HW pin.

When LOW is detected, reset hardware generates an interrupt to processors (A53SS/R5FSS/M4FSS) so they can complete the reset isolation sequence before reset is propagated.

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to MAIN domain.

MCU IOs are not affected.

When MCU domain is not configured as independent, then this reset will also warm reset MCU domain.

MAIN Domain Effect

This is a MAIN domain warm reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for warm reset isolated modules and MAIN domain CTRLMMR register bits which are reset only on MAIN_PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in the CTRLMMR reset source register **CTRLMMR_RST_SRC**. After reset is de-asserted, device will boot-up. During device boot-up, DM R5F secondary boot loader will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU M4F processor accordingly.

Reset Sequence

The RESET_REQz reset sequence is described below.

RESET_REQz Sequence shows the timing between the RESET_REQz reset signal and the internal RESETz (MAIN domain warm reset) signal. Refer to the datasheet for timing and pulse width requirements.

Copyright © 2024 Texas Instruments Incorporated

MAIN WARM RESET (RESET_REQz Pin)

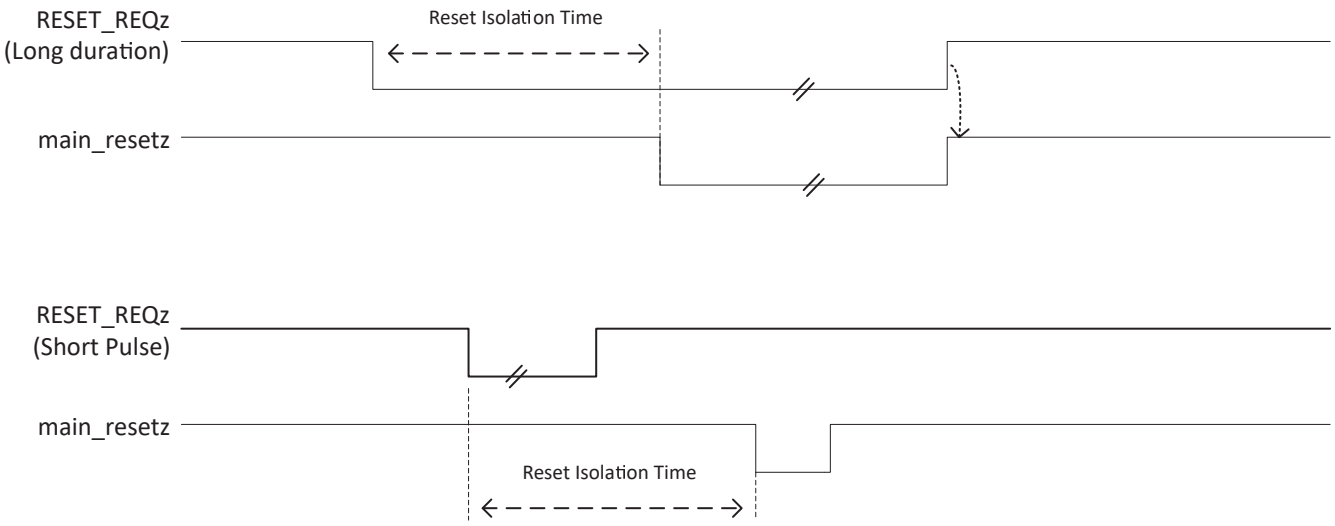

Figure 6-23. RESET_REQz Sequence

Additional Reset Details

RESETSTATz:

The RESETSTATz pin indicates the MAIN domain internal reset status (active LOW). This is a reflection of the reset status after the RESET_REQz reset signal (RESET_REQz HW Pin) is asserted.

When LOW, it indicates that the MAIN domain is in internal reset state.

When HIGH, it indicates that the MAIN domain is out of internal reset state.

RESETSTATz Timing shows the timing between the RESET_REQz reset signal and the RESETSTATz output. Refer to the datasheet for timing and pulse width requirements.

6.3.5.2.3 SW_MAIN_WARMRSTz Reset

Reset Overview

This reset is software controlled MAIN domain warm reset defined in **CTRLMMR_RST_CTRL** and **CTRLMMR_MCU_RST_CTRL**.

The M4FSS can issue a warm reset to the MAIN domain, by writing to the MCU domain CTRLMMR register.

The MAIN domain processors can issue a warm reset the WKUP domain, by writing to the MAIN domain CTRLMMR register.

Note

When M4FSS is configured as safety processor it must be reset isolated from this MAIN domain warm reset.

A reset isolation sequence for MCU domain has to be complete prior to this reset propagation.

WKUP domain CTRLMMR and MCU domain CTRLMMR registers define a 4-bit field, SW_MAIN_WARMRST[3:0] for generating a software controlled warm reset for the MAIN domain (SW_MAIN_WARMRSTz).

When SW_MAIN_WARMRST[3:0] field is set to “0110”, a MAIN domain warm reset is active (SW_MAIN_WARMRSTz = LOW).

When SW_MAIN_WARMRST[3:0] is set to any other value, the MAIN domain warm reset is inactive (SW_MAIN_WARMRSTz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

Note

This software reset is equivalent to RESET_REQz reset signal (RESET_REQz HW Pin) functionality.

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

MAIN Domain Effect

This is a MAIN domain reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for reset isolated modules and MAIN domain CTRLMMR register bits which are reset only on MAIN_PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in MAIN domain CTRLMMR reset status register **CTRLMMR_RST_STAT**. After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/M4FSS processor accordingly.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.2.4 MCU_RESETz Reset

Reset Overview

The MCU_RESETz signal is the warm reset input (active low) to the entire device, controlled by the MCU_RESETz HW Pin.

When active, it resets all modules in the MCU and MAIN domains.

MCU_RESETz will not reset selected **CTRLMMR_RST_CTRL** and **CTRLMMR_MCU_RST_CTRL** register bits. These bits are only reset by PORz.

MCU Domain Effect

All modules in MCU domain are reset except for **CTRLMMR_MCU_RST_CTRL** bits which are reset only on MCU_PORz.

IOs are not affected.

M4FSS is reset.

When MCU_RESETz is de-asserted, the MCU domain needs to be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only by PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in the CTRLMMR reset source register **CTRLMMR_RST_SRC**.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/M4FSS processor accordingly.

Additional Details

MCU_RESETSTATz:

This pin indicates internal MCU_RESETz reset status (active LOW).

When LOW, it indicates that the device, both MCU and MAIN domains, are in internal reset state.

When HIGH, it indicates that the device MAIN domains, are is out of internal reset state.

Note

In order for the MAIN domain to come out of reset, RESETz_REQ (RESET_REQz HW Pin) must also be de-asserted.

Note

For more details see MCU_RESETSTATz Status Pin.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.2.5 SW_MCU_WARMRSTz Reset

Reset Overview

This is a software MCU domain warm reset defined in MCU domain CTRLMMR.

MCU CTRLMMR defines a 4-bit field, SW_MCU_WARMRST[11:8] for generating a software warm reset in the MCU domain (SW_MCU_WARMRSTz).

When SW_MCU_WARMRST[11:8] field is set to “0110”, MCU warm reset is active (SW_MCU_WARMRSTz = LOW).

When SW_MCU_WARMRST[11:8] is set to any other value, MCU warm reset is inactive (SW_MCU_WARMRSTz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

Note

This software reset is equivalent to MCU_RESETz warm reset signal (MCU_RESETz HW Pin) functionality.

MCU Domain Effect

All modules in the MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected.

M4FSS processor is reset.

When MCU_RESETz is de-asserted, the MCU domain needs to be reconfigured by the R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in CTRLMMR reset source register**CTRLMMR_RST_SRC**.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/M4FSS processor accordingly.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.3 SMS Resets

6.3.5.3.1 SMS_WARM_OUT_RST_n Reset (MAIN Domain)

Reset Overview

The SMS will issue this reset upon a security error.

When this reset is enabled in MAIN domain, it causes a MAIN domain warm reset.

This is a synchronous reset type (needs to complete reset isolation sequence).

Note

This reset behavior is same as the RESETz_REQ reset signal (RESET_REQz HW Pin).

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

MAIN Domain Effect

This is a MAIN domain warm reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for CTRLMMR register bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in CTRLMMR reset source status register **CTRLMMR_RST_SRC**. After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/M4FSS processor accordingly.

6.3.5.3.2 SMS_COLD_OUT_RST_n Reset (MAIN Domain)

Reset Overview

This reset is a MAIN domain warm reset that is executed from the SMS. This is an asynchronous reset type (takes effect immediately). This SMS reset of the Main domain is enabled only when the SMS_COLD_RESET_EN_z bit in WKUP domain CTRLMMR is '0'.

Note

This reset behavior is same as the RESETz_REQ reset signal (RESET_REQz HW Pin) with the exception that it takes effect immediately without need for any reset isolation sequence.

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

Copyright © 2024 Texas Instruments Incorporated

MAIN Domain Effect

This is a MAIN domain asynchronous warm reset. Propagates immediately wihout any reset isolation sequence.

All modules in MAIN domain are reset except CTRLMMR register bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in CTRLMMR reset status register. After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/M4FSS processor accordingly.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.3.3 SMS_COLD_OUT_RST_n Reset (MCU Domain)

Reset Overview

The device SMS will issue this reset upon a security error.

When this reset is enabled in MCU domain, it causes a whole device warm reset.

This SMS reset of the MCU domain is enabled only when the SMS_COLD_RESET_ENz bit in MCU domain CTRLMMR is '0'.

When the M4FSS is configured as a safety processor, it can block this reset from resetting the MCU domain.

This is an asynchronous reset type (takes effect immediately)

Note

This reset behavior is same as MCU_RESETz reset signal (MCU_RESETz HW Pin).

MCU Domain Effect

All modules in MCU domain are reset except for CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected.

M4FSS is reset.

When MCU_RESETz is de-asserted, the MCU domain will be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in the CTRLMMR reset source register **CTRLMMR_RST_SRC**.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/M4FSS processor accordingly.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.4 VTM Thermal Alert Reset

Reset Overview

The VTM module outputs an alert signal (THERM_MAXTEMP_OUTRANGE_ALERT), when the device temperature goes beyond a maximum threshold.

This reset signal creates a MCU domain warm reset.

VTM alert will be active as long as the error condition (Device Temperature > Maximum Temperature Threshold) is still TRUE.

When the error goes away, VTM alert will be de-asserted and device will come out of warm reset.

Note

This signal, when asserted HIGH, will cause a device warm reset similar to MCU_RESETz.

MCU Domain Effect

All modules in MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected.

This reset is active as long as the VTM alert is active.

When THERM_MAXTEMP_OUTRANGE_ALERT is de-asserted, the MCU domain needs to be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on MAIN_PORz.

IOs are not affected.

All processor cores are reset (A53SS and R5FSS).

When THERM_MAXTEMP_OUTRANGE_ALERT is de-asserted, the device goes through full initialization procedure. The reason for this reset is captured in the CTRLMMR reset source register **CTRLMMR_RST_SRC**.

Additional Reset Details

VTM alert use-case example:

VTM sends out a warning signal before generating the Max Temp Alert.

There are 2 different threshold settings for max temperature limits.

The first one has a lower threshold which will generate an interrupt to the processor for taking action to reduce frequency, turn-off power domains, etc. This should eventually lower the temperature and avoid the Max Temp Alert.

If the interrupt does not fix the rising temperature, then VTM will issue a Max Temp Alert. This will cause a device warm reset. The VTM Max Temp Alert will be active as long as die temperature is above the programmed threshold.

Device warm reset will default certain power domains to off mode (default at power-up). This should eventually lower the die temperature further.

Software can read the reset status register to poll on the cause of the warm reset. If it is from VTM, then it can wait for additional time before turning on the power domains.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.5 MAIN ESM_ERRORz Reset

Reset Overview

This reset is issued when a MAIN domain processor (A53SS, SMS, or R5FSS) detects a catastrophic software error or a MAIN domain WDT timeout event occurs.

Errors in the MAIN domain cause the MAIN ESM module to trigger ESM_ERRORz.

This is routed as internal MAIN domain warm reset when enabled by the WKUP domain CTRLMMR reset control bit (MAIN_ESM_ERROR_RST_ENz).

This is an asynchronous reset type (takes effect immediately).

Reset MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

Reset MAIN Domain Effect

All modules in MAIN domain are reset except for MAIN domain CTRLMMR bits which are reset only on PORz.

IOs are not affected.

The device will re-boot. During boot-up, the R5FSS (secondary boot loader) will poll the CTRLMMR reset registers and reconfigure the MCU domain/M4FSS processor accordingly.

Note

If the device boot fails, and the MCU_ERRORn level is still LOW, then an external safety device should issue the MCU_PORz Reset to allow the device to recover from this error.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.6 MCU ESM_ERRORz Reset

Reset Overview

This reset is issued when the M4FSS detects a catastrophic safety error or a MCU WDT timeout occurs.

Errors in the MCU domain cause the MCU ESM module to trigger error output.

This is routed as a device warm reset when enabled by the MCU domain CTRLMMR bit (MCU_ESM_ERROR_RST_ENz).

This is an asynchronous reset type (takes effect immediately).

MCU Domain Effect

All modules in MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on PORz.

IOs are not affected.

Error is reported on MCU_ERRORn pin.

When SAFETY_ERROR_RST_n is de-asserted, the MCU domain needs to be reconfigured by the R5FSS (secondary boot loader) in the MAIN domain.

External hardware (PMIC or secondary MCU safety channel) must issue MCU_PORz to recover from this error.

MAIN Domain Effect

All modules in MAIN domain are reset except for reset isolated modules and MAIN domain CTRLMMR bits which are reset only on PORz.

IOs are not affected.

Device will re-boot. During boot-up, the R5FSS (secondary boot loader) will poll the CTRLMMR reset source register and configure the MCU domain/M4FSS processor accordingly.

If the device boot fails, and MCU_ERRORn level is still LOW, then an external safety device should issue the MCU_PORz reset to allow the device to recover from the error.

6.3.5.7 DM_WDT_RST_n Reset

Reset Overview

During Deeplseep resume sequence if the Device Manager is unable to respond due to a software bug, the WKUP domain WDT timer will issue this reset signal.

When this reset is enabled in MCU domain, it causes a whole device warm reset.

This WKUP WDT reset is enabled only when the DM_WDT_RST_EN_z bit in MCU domain CTRLMMR is '0'.

When the M4FSS is configured as a safety processor, it can block this reset from resetting the MCU domain. This is an asynchronous reset type (takes effect immediately)

Note

This reset behavior is same as MCU_RESETz reset signal (MCU_RESETz HW Pin).

MCU Domain Effect

All modules in MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected. M4FSS is reset.

Copyright © 2024 Texas Instruments Incorporated

When this reset is de-asserted, the MCU domain will be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When this reset is de-asserted, the device goes through full boot. The reason for this reset is captured inthe CTRLMMR reset source register.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/M4FSS processor accordingly.

Copyright © 2024 Texas Instruments Incorporated

6.3.5.8 HHV

IOs support HHV mode during power up. HHV is active when PORz signal is driven LOW.

HHV allows IO cells to be tri-stated and is an IO feature. All IO cells have HHV which is asserted (driven) by HHV generated during PORz assertion. There are default pull values during this HHV/PORz assertion specified in the device Datasheet for each pin. All HHV logic controlling the buffer output enable and associated default internal pull for each IO will be applied.

HHV Timing Diagram demonstrates the timing sequence for the device HHV signals.

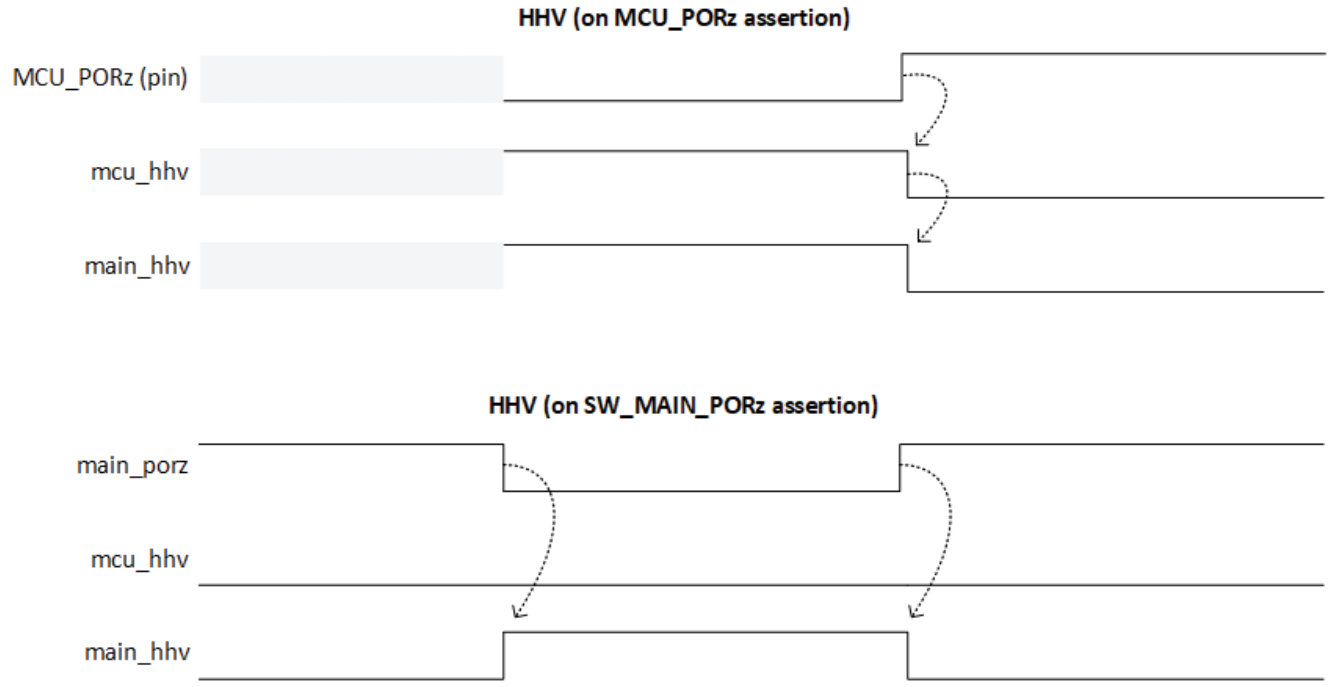

Figure 6-25. HHV Timing Diagram

6.3.5.9 BOOTMODE Pin Latching

This device requires several Boot Mode controls to enable device boot. The BOOTMODE inputs are not implemented on dedicated pins. They are multiplexed with other signal functions, where pins associated with the BOOTMODE inputs are defined in the Pin Attributes table. The logic state of the BOOTMODE inputs are latched on the rising edge of PORz_OUT. Valid logic states must be maintain as long as PORz_OUT is held low. The latched values are reflected in WKUP CTRL MMRs for read/write access.

Copyright © 2024 Texas Instruments Incorporated

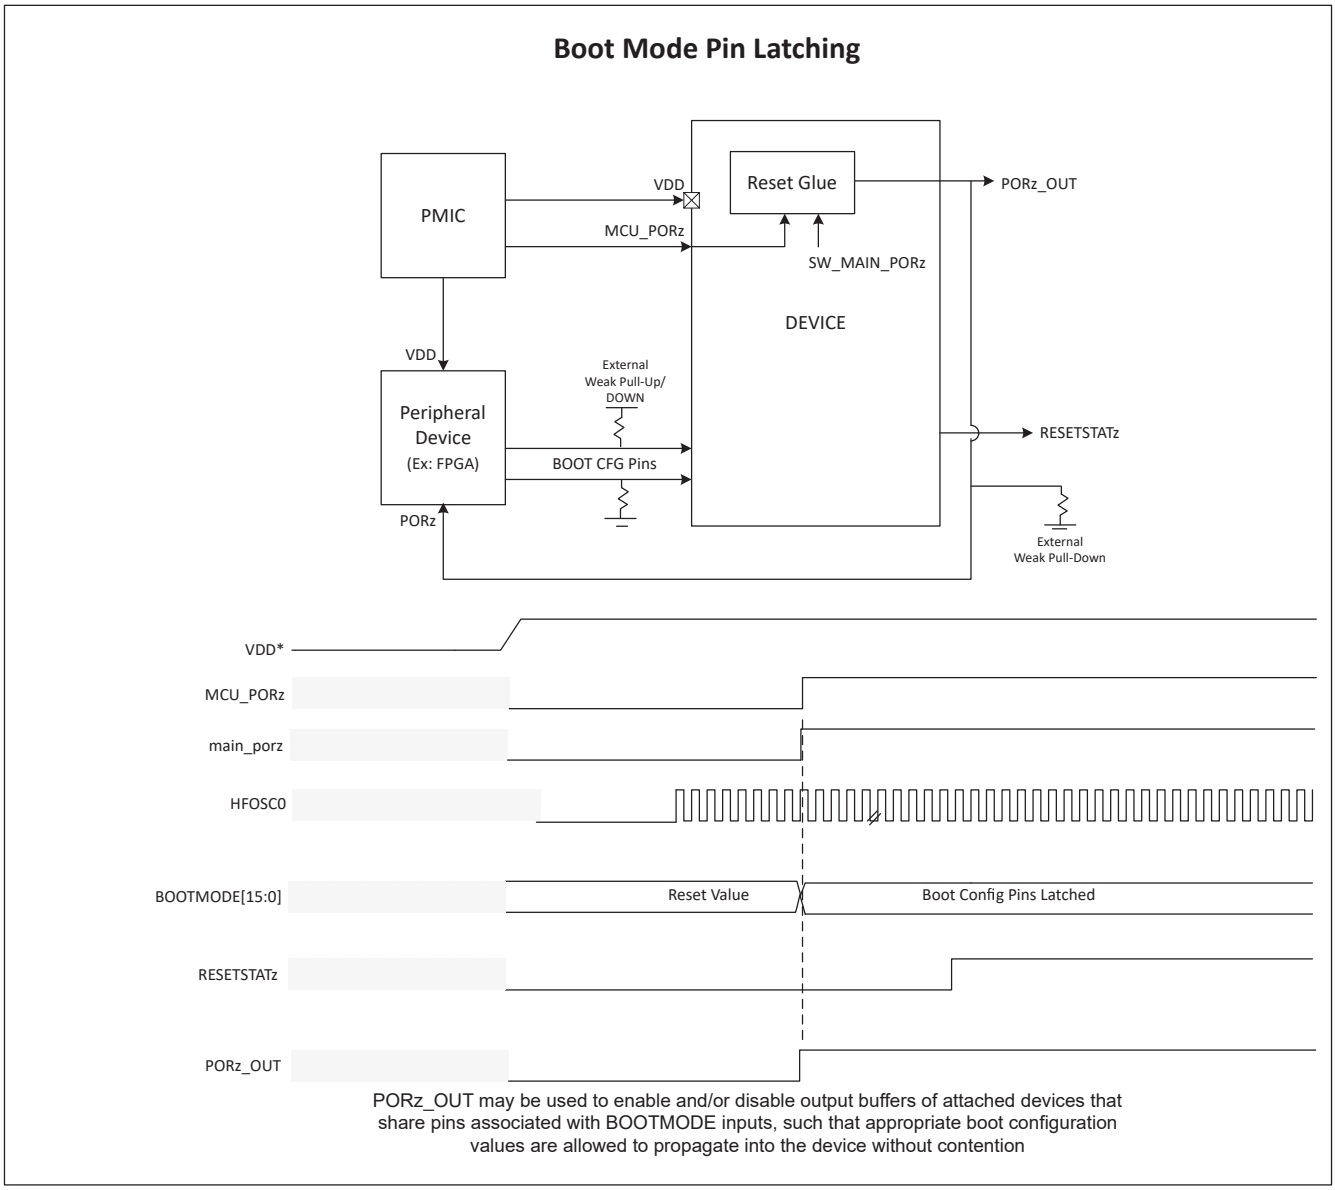

Figure 6-26. BOOTMODE Pin Latching

6.3.5.10 Power-on-Reset Sequence

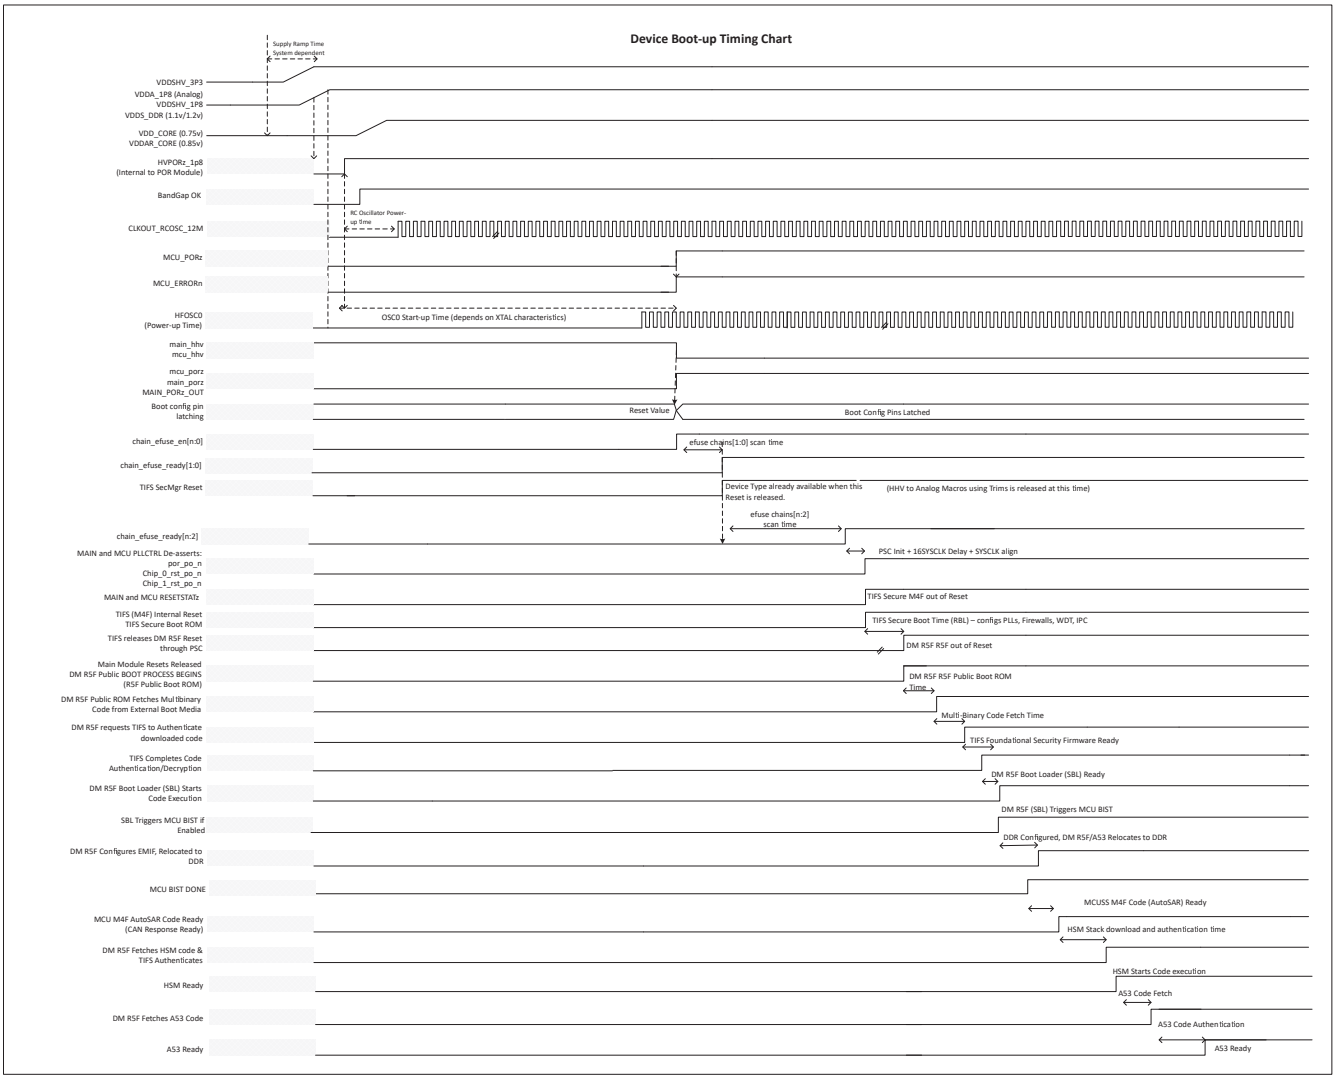

Figure 6-28. Power-up/Boot Timing Chart

6.3.5.11 Low Power Mode Reset Handling

This device supports Low Power & Deepsleep modes where parts of the device are switched-off through internal Power-Domain switches. To support these low power modes the device is partitioned so that only a small region is kept active (Wake-up) and the rest can be powered off through power-down switches. During deepsleep mode, several power-domains in Main domain are powered off and its PORz will be asserted.

Figure 6-29 shows the high-level overview of Power domain partitions.

Copyright © 2024 Texas Instruments Incorporated

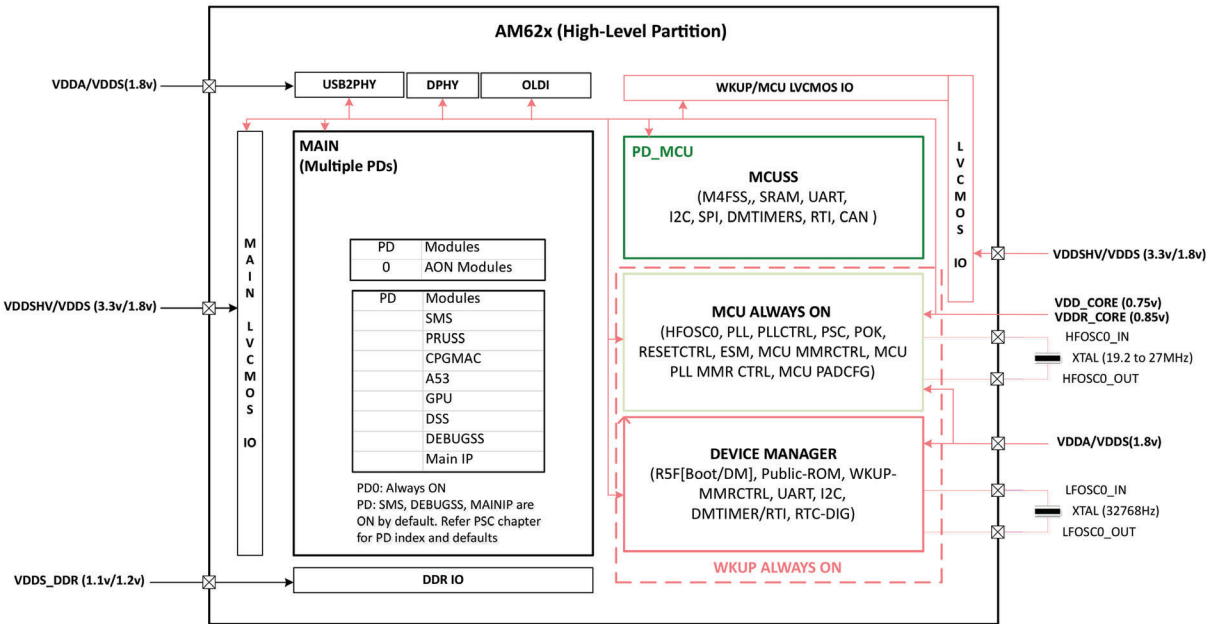

Figure 6-29. Power Domain Partitions

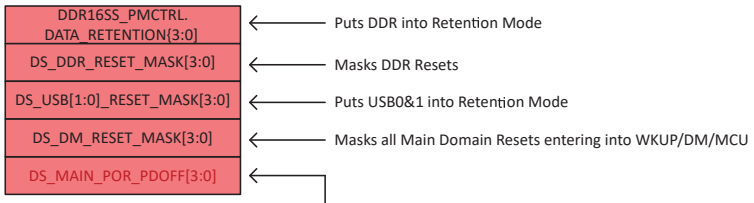
Copyright © 2024 Texas Instruments Incorporated

WKUP MMR DEEP SLEEP CONTROLS

These bits are multi-bit encoded fields (ideally 4 bits) to prevent single bit flip/error from causing a reset. When this 4bit MMR filed is programmed with a value of 4'b0110, the decode logic must make that signal active ('1'). For all other values, the decode logic makes reset inactive. The default value must be 4'b1111, which is reset inactive. These MMRs are key-lock protected and firewall protected. Reset control for these MMRs is MCU PLLCTRL CHIP_1_RST_n



When DS_MAIN_POR_PDOFF is programmed high (towards the end of Deepsleep sequence), this signal is used to assert main_porz (=Low) and also force ds_pd_sms_off, ds_pd_debugss_off, ds_pd_mainip_off to off state (= '0'). This MMR is programmed only during Deepsleep mode.

Rising edge of DS_MAIN_POR_PDOFF is captured into WKUP MMR SLEEP STATUS MMR as Main Domain DeepSleep State. When Main domain resumes from Deepsleep, TIFS can read this MMR to detect that it is resuming from deeplseep state. TIFS can clear this bit or can request DM to clear this bit.

Since DS_MAIN_POR_PDOFF is also causing a Main Domain Porz during deeplseep mode, inverted version of DS_MAIN_POR_PDOFF should be captured as ds_main_porz in Reset Status MMR in MCU CTRL MMR.

High Level Sequence

6.4 Clocking

This chapter describes the clock architecture of the device.

6.4.1 Overview

To satisfy the various subsystems requirements, the device features multiple clock sources and clock generators:

- External Crystal Driver
- Internal Oscillator
- Phase-Locked Loop circuits (PLLs)
- Dividers

Figure 6-32 shows the device top-level clock diagram. The clocking is divided into two clocking domains - MCU and MAIN.

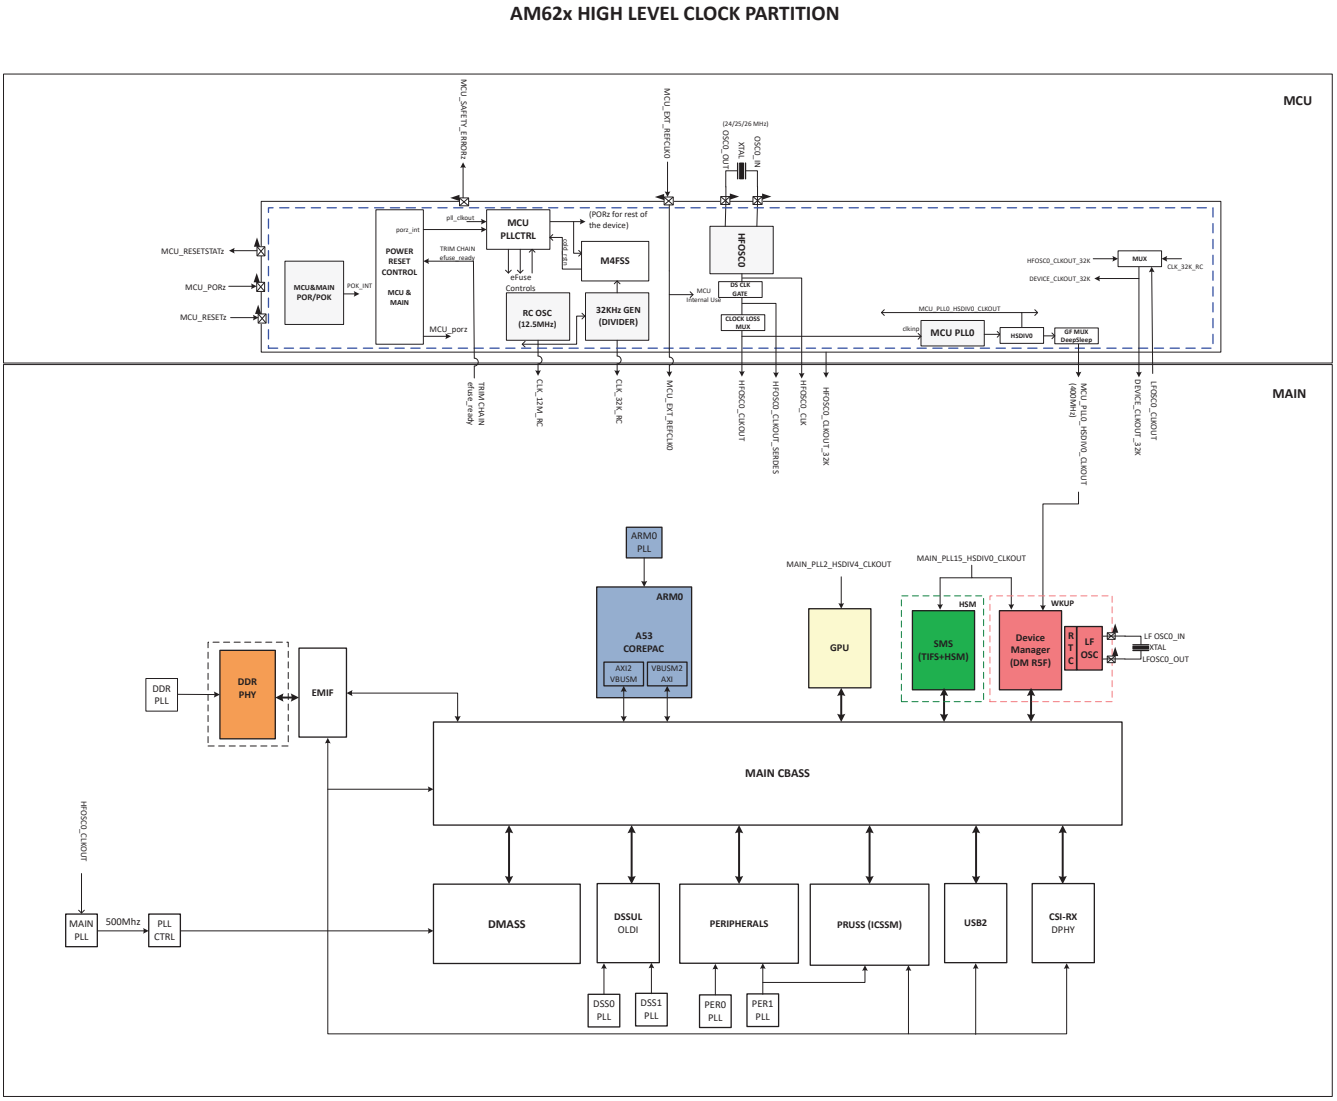

Figure 6-32. Top-Level Clock Diagram

Copyright © 2024 Texas Instruments Incorporated

6.4.2 Clock Inputs

6.4.2.1 Overview

Various external clock inputs are needed to drive the device. Summary of these input clock signals is as follows:

- High frequency oscillators
  - MCU_OSC0_XO/MCU_OSC0_XI — external main crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to PLLs within MCU and MAIN domain.
- Low frequency oscillators
  - LSOSC0_IN/LFOSC0_OUT - external 32.768KHz crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to RTC and Timers within MCU and MAIN domain.
- General purpose clock inputs
  - MCU_EXT_REFCLK0 — optional external system clock input (MCU domain).
  - EXT_REFCLK1— optional external system clock input (MAIN domain).
- External CPTS reference clock inputs
  - CP_GEMAC_CPTS0_RFT_CLK — CPTS reference clock input for CPSW and Timers in MAIN.
- External audio reference clock inputs/outputs
  - AUDIO_EXT_REFCLK[1:0] — optional McASP high-frequency input clocks when configured to operate as an input.

Note

Other clock inputs that are routed directly to the subsystems are described in the respective subsystem chapters.

Copyright © 2024 Texas Instruments Incorporated

6.4.3 Clock Outputs

The device provides several system clock outputs. Summary of these output clock signals is as follows:

- MCU_SYSCLKOUT0
- MCU_OBSCLK0
- SYSCLKOUT0
- OBSCLK0
- WKUP_CLKOUT0
- CLKOUT0
- AUDIO_EXT_REFCLK[1:0]

Other clock outputs, that are routed directly from subsystems to device pins, are described in the respective module chapter.

Observation clock pins - MCU_OBSCLK0 and OBSCLK0 serve the following purposes:

- During testing, PLLs on the device are configured to output all operating frequencies desired by each module to characterize PLL performance.
- System debug: during debug, clocks from various PLLs can be inspected for possible clues. Example clock glitches, lock loss etc.

Note

Maximum frequency supported on both MCU_OBSCLK0 and OBSCLK0 pins is 200 MHz. Hence the divider at the output of each OBSCLK mux must be programmed to meet this limitation.

Unlike the OBSCLK pins which can select several different clocks for output, system clock pins (MCU_SYSCLKOUT0 and SYSCLKOUT0) are hardwired to dedicated clock resources (see Section 6.4.3.2)

6.4.3.1 Observation Clock Pins

6.4.3.1.1 MCU_OBSCLK0 Pin

MCU_OBSCLK0 output is controlled by MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL register in the MCU_CTRL_MMR0 module; for more information about control registers, refer to *Control Module (CTRL_MMR)*. Two muxes are connected in series - MCU_OBSCLK0_MUX0 and MCU_OBSCLK0_MUX1, see Figure 6-33.

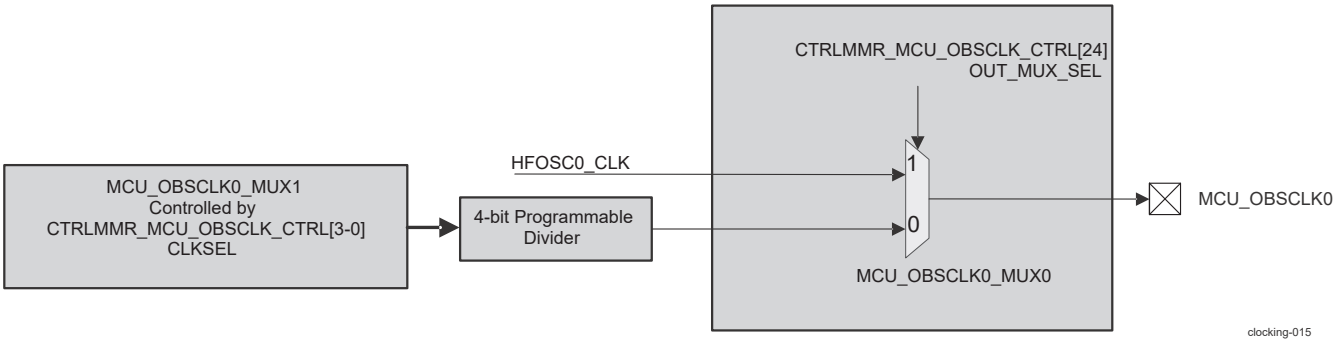

Figure 6-33. MCU_OBSCLK Muxes Diagram

How to select the output of MCU_OBSCLK0_MUX1 is described in Table 6-24.

Table 6-24. MCU_OBSCLK0_MUX1 Output Clock Selection

(1) Software-controlled 4-bit divider is used to obtain the divided versions of the clocks passed to MCU_OBSCLK1 mux
(2) For more information about control registers, refer to *Control Module (CTRL_MMR)*.
(3) GND - ground

The value of the software-controlled 4-bit divider is determined by the MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL[11-8] CLK _DIV field; for more information about control registers, see *Control Module (CTRL_MMR)*.

Note

MCU_OBSCLK1_MUX0 is provided as a low jitter output for HFOSC0_CLK. In this configuration, MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL[3-0] should be configured as 0x1 (1, selecting a logical low signal) and MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL[24] should be configured as 0x1.

6.4.3.1.2 OBSCLK0 Pin

The OBSCLK0 output pin is controlled by MAIN_CTRL_MMR_CFG0_OBSCLK0_CTRL register in the CTRL_MMR0 module; for more information about control registers, refer to *Control Module (CTRL_MMR)*. Figure 6-34 shows a block diagram of internal OBSCLK0 mux connections.

(2) For more information about control registers, refer to *Control Module (CTRL_MMR)*.
(3) GND - ground

The value of the software-controlled 8-bit divider is determined by register MAIN_CTRL_MMR_CFG0_OBSCLK0_CTRL[15-8] CLK_DIV; for more information about control registers, refer to *Control Module (CTRL_MMR)*.

6.4.3.1.3 AUDIO_EXT_REFCLK

AUDIO_EXT_REFCLK gives an option of sourcing one of six McASP high-frequency audio reference clocks, MAIN_PLL1_HSDIV6_CLKOUT, or MAIN_PLL2_HSDIV8_CLKOUT when configured to operate as an output.

6.4.3.2 System Clock Pins

6.4.3.2.1 MCU_SYSCLKOUT0

MCU_SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (MCU_SYSCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

Note

MCU_SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

6.4.3.2.2 SYSCLKOUT0

SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (SYSCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

Note

SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

6.4.3.2.3 WKUP_CLKOUT0

The WKUP_CLKOUT0 output pin is controlled by the WKUP_CTRL_MMR_CFG0_CLKOUT_CTRL register in the WKUP_CTRL_MMR0 module; for more information about control registers, refer Control Module (CTRL_MMR). Figure 6-35 shows a block diagram of internal WKUP_CLKOUT0 mux connections.

WKUP_CTRL_MMR_CFG0_CLKOUT_CTRL[1][2-0] WKUP_CLKOUT_SEL	WKUP_CLKOUT0_MUX Output Clock Selection
0x3	MAIN_PLL1_HSDIV2_CLKOUT
0x4	MAIN_PLL2_HSDIV9_CLKOUT
0x5	DEVICE_CLKOUT_32K
0x6	CLK_12M_RC
0x7	HFOSC0_CLKOUT

(1) For more information about control registers, refer Control Module (CTRL_MMR).

6.4.4 Device Oscillators

The device has the possibility to source clocks of an external high-frequency oscillator - HFOSC0 and external 32.768KHz oscillator - LFOSC0. The device has also one internal RC oscillator - CLK_12M_RC.

6.4.4.1 Device Oscillators Integration

6.4.4.1.1 High-Frequency Oscillator with External Crystal

By default, HFOSC0 is enabled after PORz. It supports a bypass mode. In this mode, an external clock can be driven on the XI Pin.

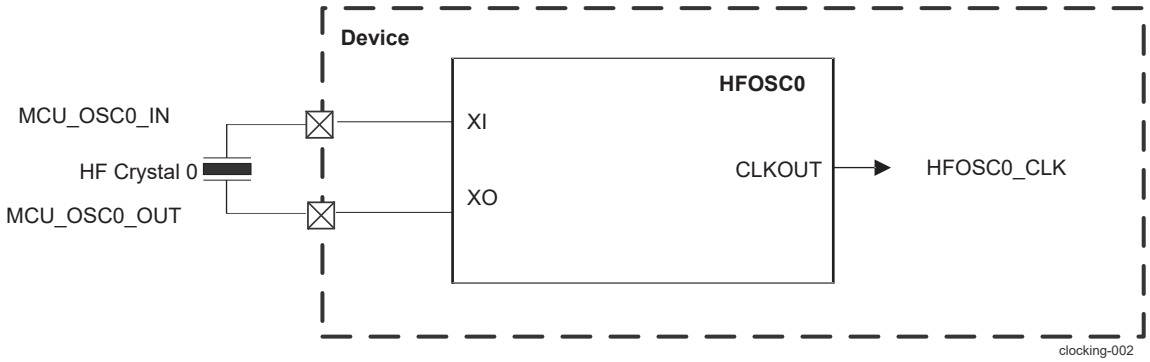

Figure 6-36. HFOSC0 Integration Diagram

6.4.4.1.2 Low-Frequency Oscillator with External Crystal

By default, LFOSC0 is disabled after PORz. It supports a bypass mode. In this mode, an external clock can be driven on the XI Pin.

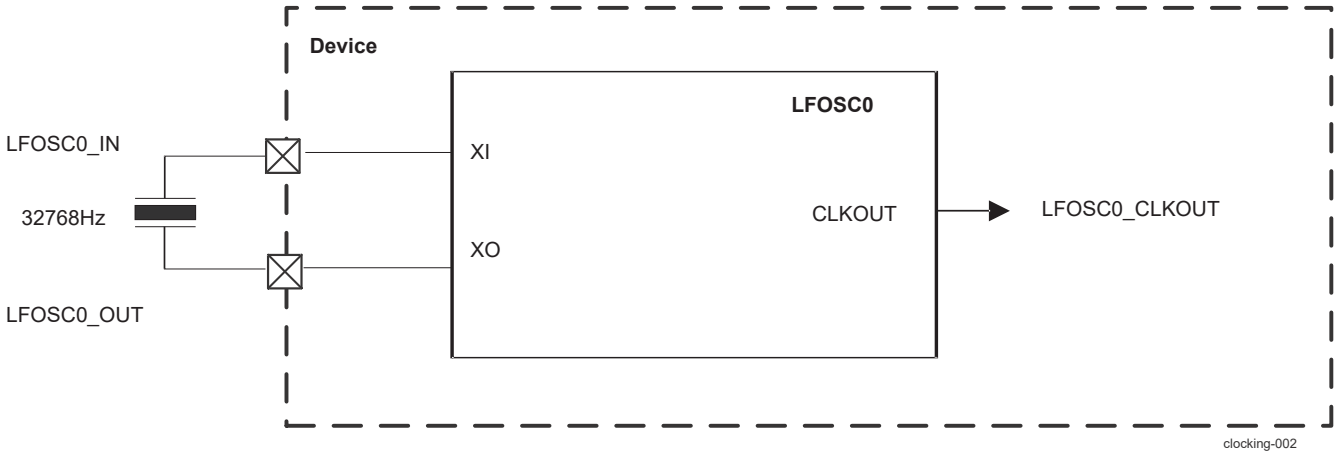

Figure 6-37. LFOSC0 Integration Diagram

Copyright © 2024 Texas Instruments Incorporated

6.4.4.1.3 Internal RC Oscillator

CLK_12M_RC in always oscillate mode.

The 12.5-MHz RC clock output (CLK_12M_RC) is used by the on-chip Reset Glue logic, Power Reset Generator (PRG) circuits, HFOSC0 Loss Circuits, Dual Clock Comparator (DCC) and Timer Modules.

Note

An output clock of CLK_12M_RC is further divided down to generate a 32-kHz clock (CLK_32K_RC). This clock is used by SMS and Timer Modules.

The actual value of the derived CLK_32K_RC will vary with PVT variations.

6.4.4.2 Oscillator Clock Loss Detection

The device supports HFOSC0 clock loss circuitry to detect when HFOSC0_CLK stops toggling. Dedicated hardware logic monitors HFOSC0 clock using CLK_12M_RC clock. When HFOSC0_CLK stops toggling for 9 CLK_12M_RC clock periods, a HFOSC0 clock stop loss condition is detected. If CTRLMMR_MCU_PLL_CLKSEL[8] CLKLOSS_SWTCH_EN is set , the reference clock is switched from HFOSC0_CLKOUT to CLK_12M_RC to allow the device to operate with a slower clock. The HFOSC0_CLK clock loss condition is reported as an error to MCU_ESM0 regardless of the value of CTRLMMR_MCU_PLL_CLKSEL[8] CLKLOSS_SWTCH_EN. Integration diagram of HFOSC0 clock loss detection is presented in Figure 6-38.

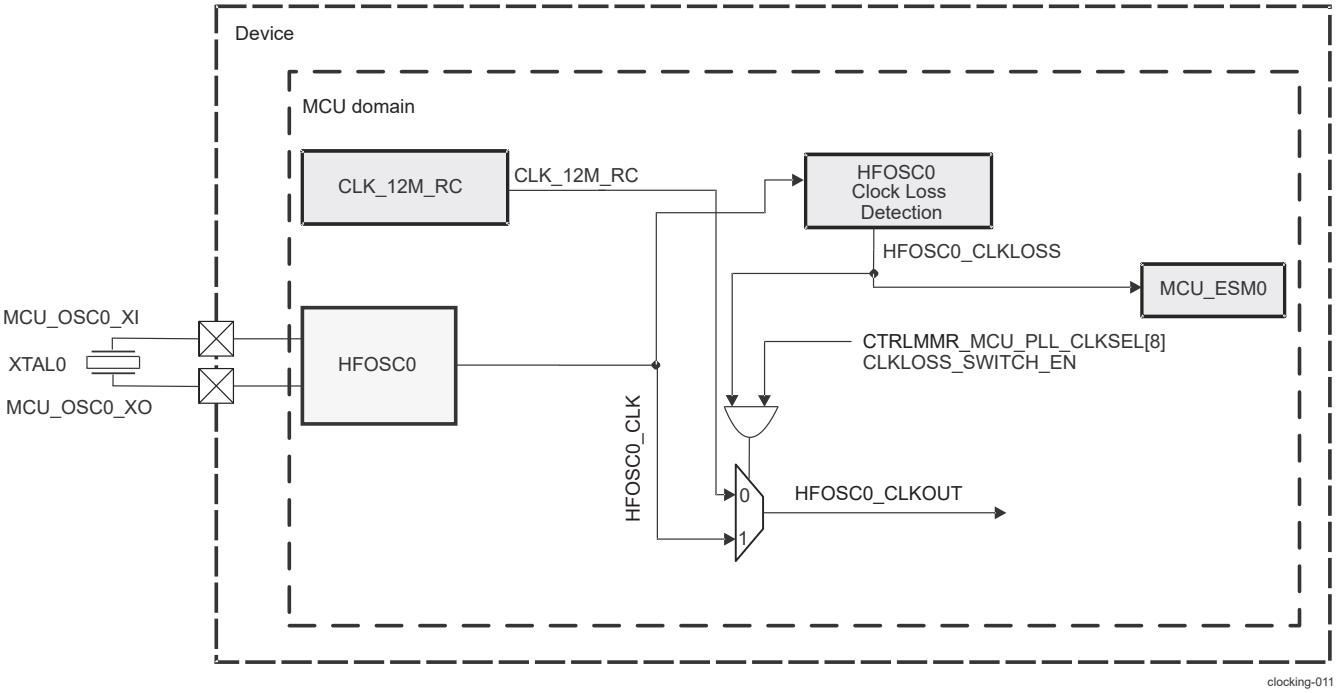

Figure 6-38. HFOSC0 Clock Loss Detection Integration Diagram

MCU_ESM0 can optionally generate an interrupt to MCU_M4FSS0 and DM_R5FSS0 so they can save some critical contents such as error logging to scratch pad memory or external flash. ESM must also be configured to report this error on the MCU_ERRORn pin.

HFOSC0 clock loss is a catastrophic failure since this clock is the most critical system clock. During the clock loss condition an external system intervention is required.

The clock loss mux is not a glitch free mux. The mux control is synchronized to the CLK_12M_RC clock. Since HFOSC0_CLK has stopped switching the mux should transition to RC Clock without producing glitches.

Copyright © 2024 Texas Instruments Incorporated

During clock-loss condition, the device reports the error to the external device through MCU_ERRORn pin - the pin is driven Low. The recovery mechanism is up to the external system (such as a PMIC to take action). For example, it can try a full system power cycle to see if the system recovers. If the system does not recover then, it has to take some other action such as to check system clocks, external crystal or supply rails.

Device PLLs will lose lock when clock loss is detected. During this time 12.5-MHz RC clock is output through the bypass muxes. The PLL will relock to a new frequency based on 12.5 MHz RC clock.

In an event of clock glitch which may potentially hang the device, then the SMS watchdog timer will expire and will generate an internal reset for the whole device.

Copyright © 2024 Texas Instruments Incorporated

6.4.5 PLLs

Phase-Locked Loop circuits (PLLs) in the device are clock generator PLLs, which multiply the lower-frequency reference clock up to the operating frequency of the respective subsystem(s).

6.4.5.1 MCU Domain PLL Overview

MCU_PLL0 (MCU PLL) with MCU_PLLCTRL0 are present in the device in MCU domain. An overview is shown on Figure 6-39. For more specific information about PLLs see Section 6.4.5.5, *PLLs Device-Specific Information*.

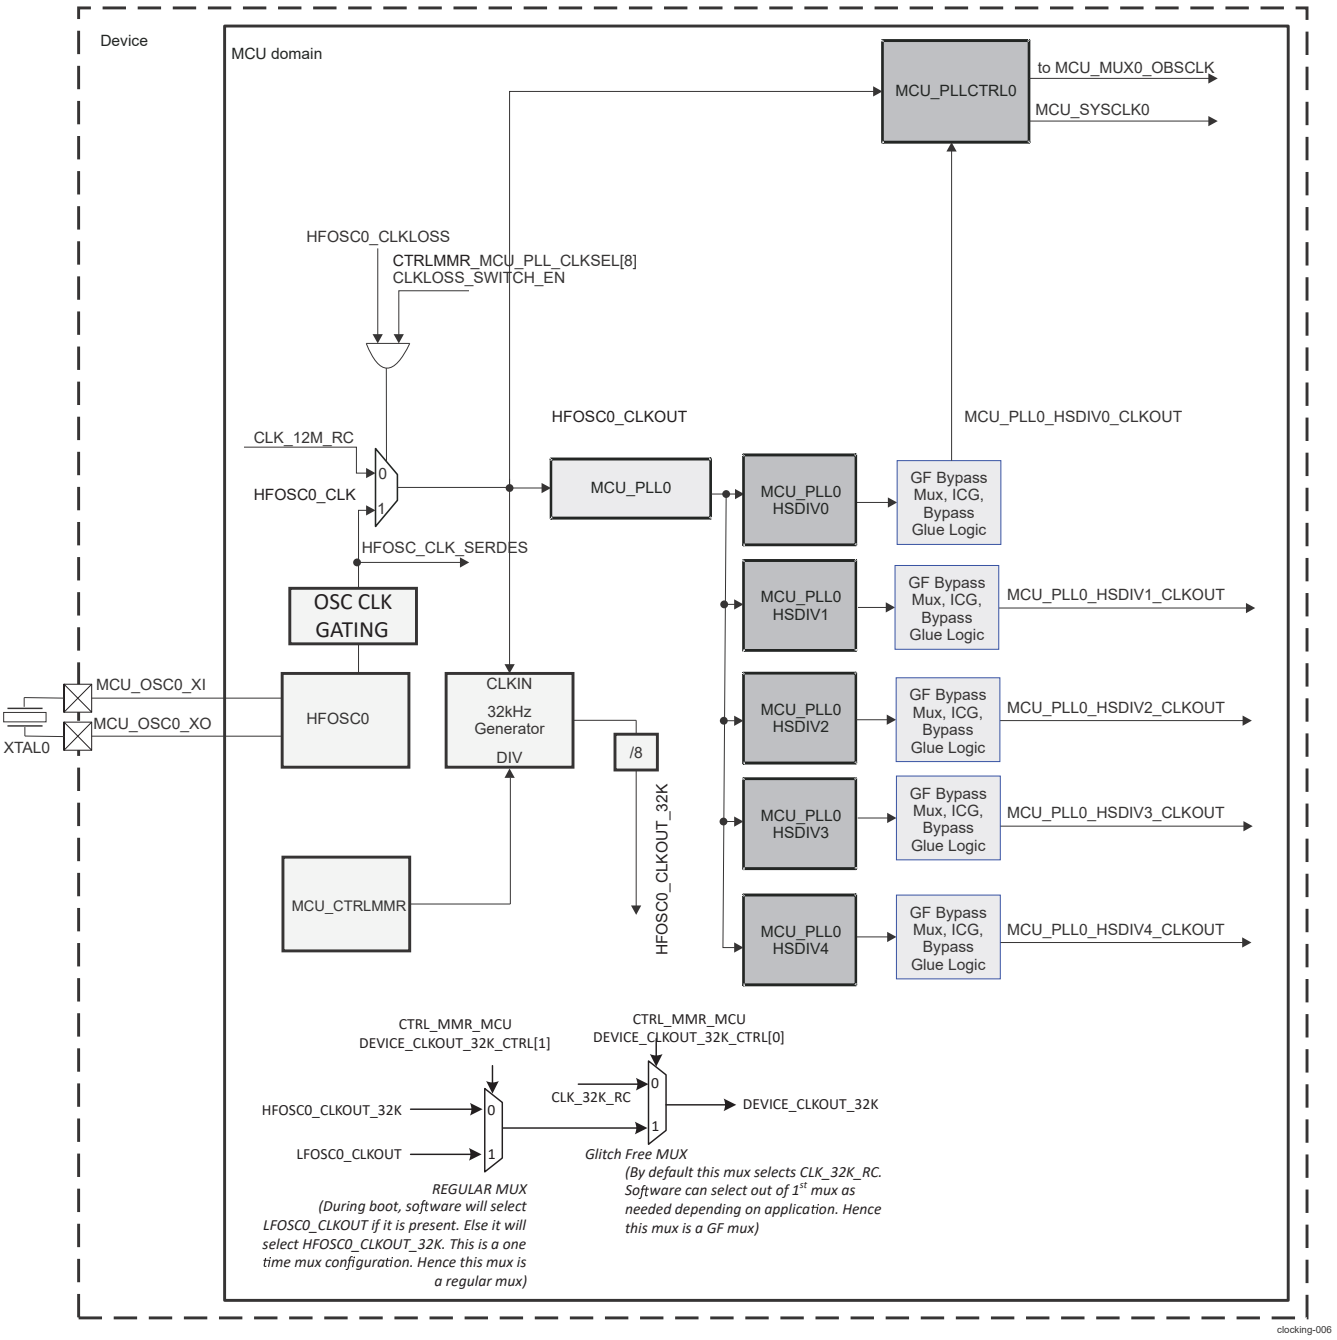

Figure 6-39. MCU Domain PLLs Integration

Copyright © 2024 Texas Instruments Incorporated

6.4.5.2 MAIN Domain PLLs Overview

The following are the PLLs in the device in MAIN domain:

- PLL0 (MAIN PLL) with PLLCTRL0
- PLL1 (PER0 PLL)
- PLL2 (PER1 PLL)
- PLL8 (ARM0 PLL)
- PLL12 (DDR PLL)
- PLL15 (SMS PLL)
- PLL16 (DSS0 PLL)
- PLL17 (DSS1 PLL)

Overview of the device PLLs with their reference clock options in MAIN domain is shown on Figure 6-40. For more specific information about PLLs see Section 6.4.5.5, *PLLs Device-Specific Information*.

Note

The external muxes of choosing the reference clocks are glitch-free muxes.

6.4.5.3 PLL Reference Clocks

6.4.5.3.1 PLLs in MCU Domain

The reference clock MCU_PLL0_REF_CLK for the PLL in MCU domain is chosen between the internal high-frequency (HF) oscillator with external crystal (HFOSC0) and 12.5-MHz free-running RC oscillator. The selection is made through CTRLMMR_MCU_PLL_CLKSEL[8] CLKLOSS_SWTCH_EN, see Table 6-27.

Table 6-27. PLL MCU Domain Reference Clock Selection - HFOSC0_CLKOUT Selection

CTRLMMR_MCU_PLL_CLKSEL(1)[8] CLKLOSS_SWTCH_EN	MCU_PLL0_REF_CLK
0 (default)	HFOSC0_CLK
1	CLK_12M_RC if clock loss is detected or HFOSC0_CLK if clock loss is not detected

(1) For more information about control registers, see *Control Module (CTRL_MMR)*.

6.4.5.3.2 PLLs in MAIN Domain

Each PLL in MAIN domain has a dedicated register (CTRLMMR_MAIN_PLLn_CLKSEL**CTRLMMR_MAIN_PLLn_CLKSEL**, n = 0 to 2, 8, 12,15, 16, 17) in CTRL_MMR0 that contains associated control bits.

6.4.5.4 Generic PLL Overview

To generate high-frequency clocks, the device supports multiple on-chip PLLs controlled directly by the Top-level Clocking. Their type is Fractional PLL with Calibration (PLLTS16FFCLAFRACF2).

Note

This chapter discusses only the PLLs that are directly controlled by the Top-level Clocking. The other PLLs embedded in and managed by other subsystems are described in their respective subsystems.

6.4.5.4.1 PLLs Output Clocks Parameters

Figure 6-41 shows the functional architecture of a generic PLL for PLLTS16FFCLAFRACF2 type.

Copyright © 2024 Texas Instruments Incorporated

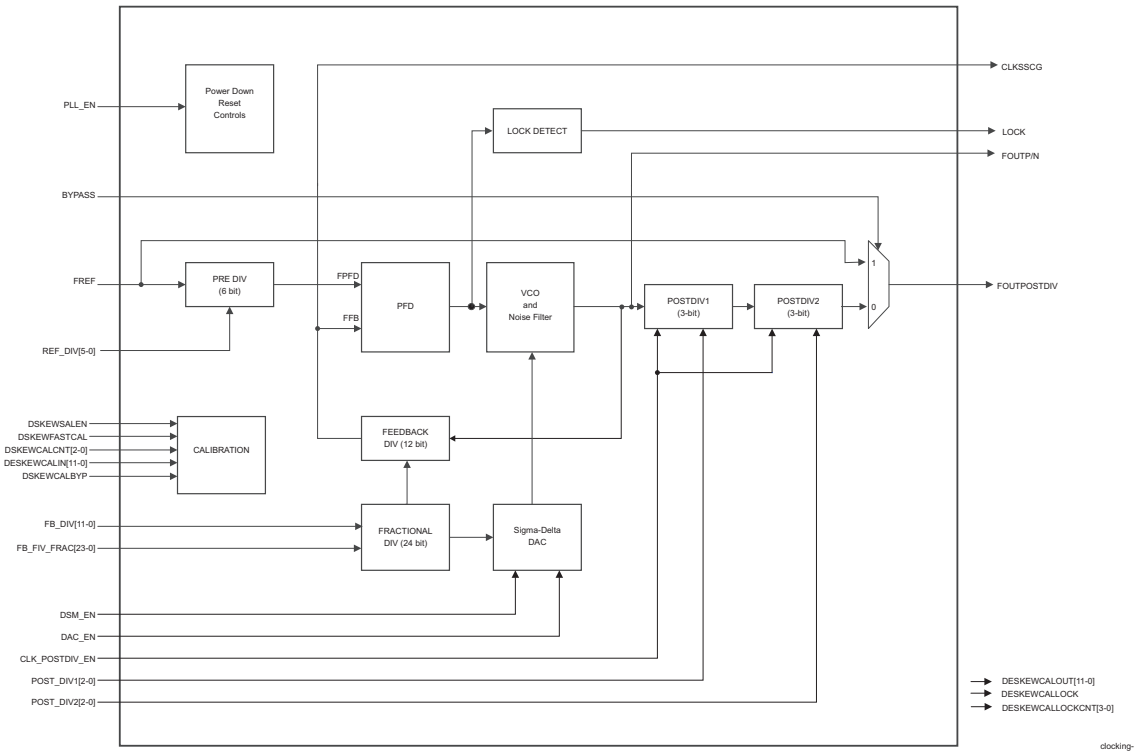

Figure 6-41. Generic PLL Functional Diagram for PLLTS16FFCLAFRACF2 Type

6.4.5.4.1.1 PLLs Input Clocks

As shown in Figure 6-41 the reference clock (FREF) input is used to generate the synthesized clock, but can also be used as the bypass clock for some outputs of the PLL whenever the PLL enters bypass mode. It is mandatory for the PLL clock synthesis.

6.4.5.4.1.2 PLL Output Clocks

6.4.5.4.1.2.1 PLLTS16FFCLAFRACF2 Type Output Clocks

Table 6-28 describes the output clocks of PLLTS16FFCLAFRACF2.

Table 6-28. PLLTS16FFCLAFRACF2 Output Clocks

Output	Description	Frequency
FOUTP	Positive phase VCO output (no post divider)	(FREF / REF_DIV) * (FB_DIV + FB_DIV_FRAC)
FOUTN	Negative phase VCO output (no post divider)	(FREF / REF_DIV) * (FB_DIV + FB_DIV_FRAC)
FOUTPOSTDIV	VCO-divided clock output.	FOUTP / (POST_DIV1*POST_DIV2)
CLKSSCG	Clock to SSMOD	(FREF / REF_DIV)

Where:

- REF_DIV is the software-configured division ratio binary value.
- FB_DIV is the software-configured division ratio binary value.
- FB_DIV_FRAC is the software-configured fractional division.
- POST_DIV1 is the software-configured division ratio binary value.
- POST_DIV2 is the software-configured division ratio binary value.

Copyright © 2024 Texas Instruments Incorporated

Note

POST_DIV1 and POST_DIV2 valid values are from 1 to 7. To ensure correct operation, POST_DIV1 must always be programmed to a value equal to or greater than POST_DIV2.

Note

For device-specific information about clock output parameters and synthesized clocks, see Table 6-33 and Table 6-34.

6.4.5.4.1.2.2 PLL Lock

PLL module outputs a lock status signal to indicate that the PLL has achieved frequency lock. When the PLL detects no cycle slips between the feedback clock (FFB) and reference clock FPFD (FREF/ REF_DIV[5-0]) for 128 consecutive cycles, it asserts the lock signal high. When the PLL detects any cycle slip, lock signal will go low and stays low until it detects no cycle slip for 128 consecutive cycles. This lock signal is captured in <PLL_name>_STAT[0] LOCK bit. Software can read this bit to determine if the PLL has achieved frequency lock before selecting the PLL clock through external bypass mux.

When PLL losses lock, there is a hardware mechanism to automatically bypass the PLL clock to the reference clock (FREF) using the external glitch free mux. BYP_ON_LOCKLOSS bit in <PLL_name>_CTRL register enables this automatic bypass mode on PLL lock loss. When the PLL re-locks, the glitch free mux switches to PLL clock out.

The PLL Lock signal is also routed to ESM module for error reporting. ESM can be configured to generate interrupts to MCU_M4FSS0 and R5FSS0/1 and assert Low on MCU_ERRORn pin on PLL Lock loss for further action.

6.4.5.4.1.2.3 HSDIVIDER

A PLL may contain up to 10 HSDIVIDER modules to produce more clocks with divided ratio based on the PLL synthesized clock frequency. HSDIVIDER provides only one output. The HSDIVIDER output clock frequency is given by the equations in Table 6-29.

Table 6-29. HSDIV_CLKOUT Frequency With PLL State

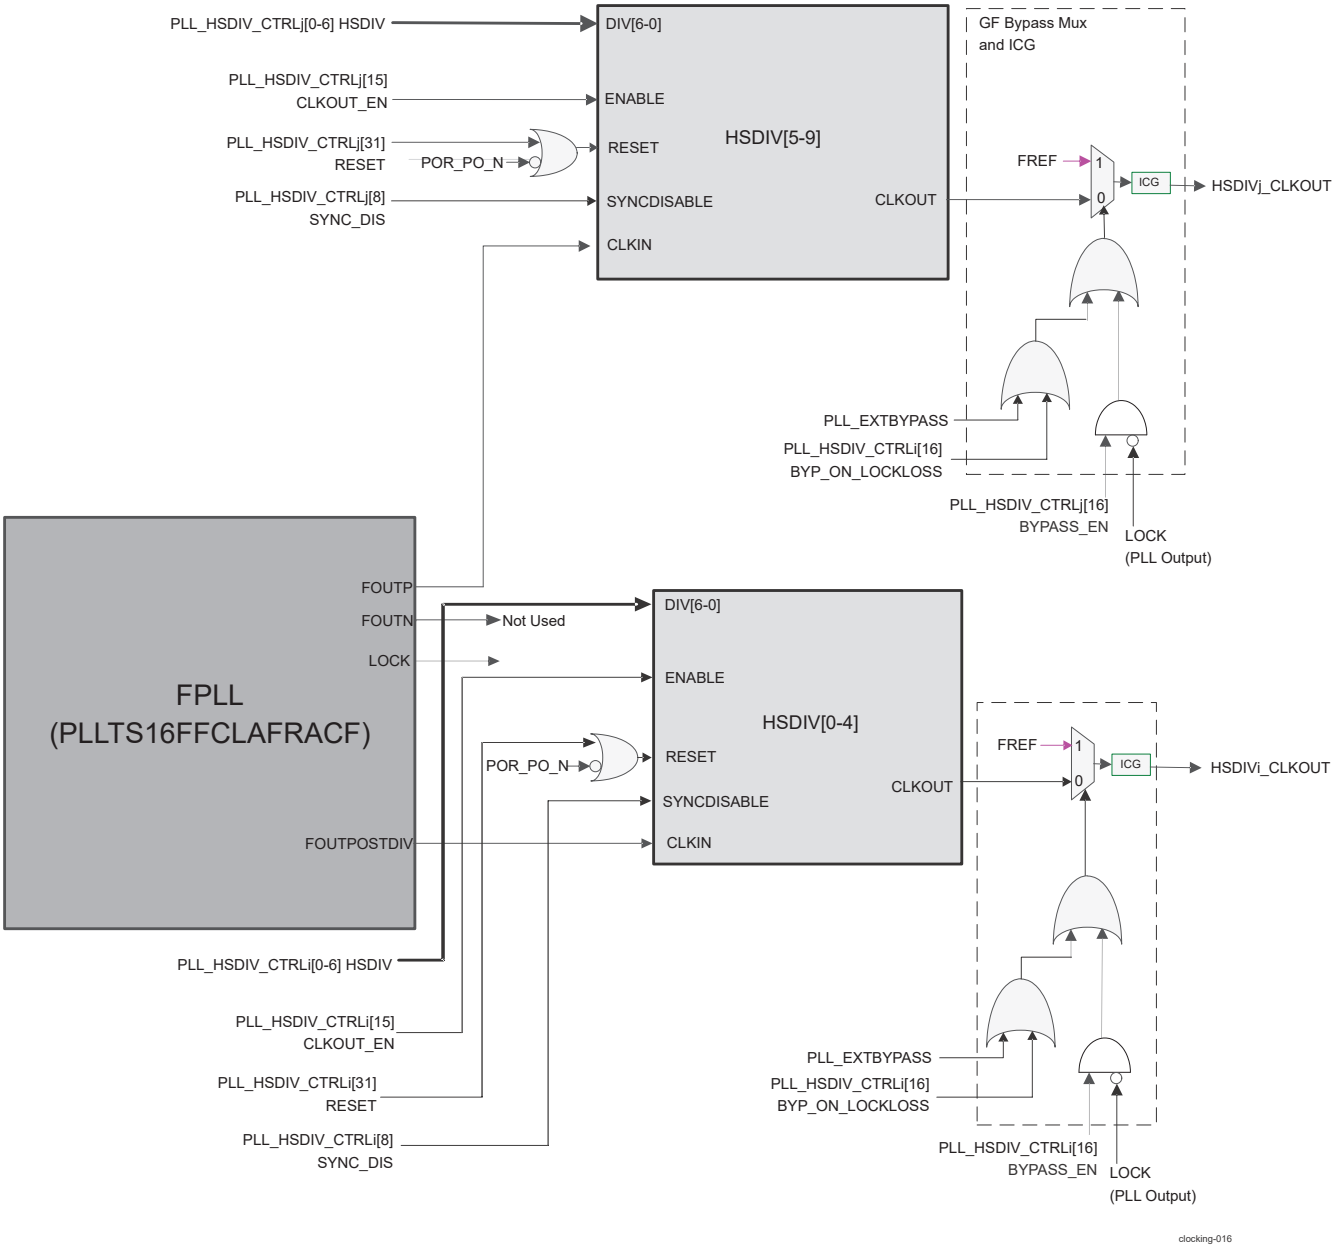
Equation	PLL Mode
HSDIV_CLKOUT = FOUTP / (HSDIV + 1)	Locked
HSDIV_CLKOUT = FREF	Before lock or during relock

Where:

- FOUTP is the PLL lock frequency.
- HSDIV is the software-configured division ratio binary value.

Figure 6-42 describes the connection between a HSDIV and a specific type of PLL. Signals related only to this connections are shown in both figures.

Copyright © 2024 Texas Instruments Incorporated



(1) i = 0 to 4; j = 5 to 9

Figure 6-42. PLLTS16FFCLAFRACF2 and HSDIV Connection

6.4.5.4.1.2.4 ICG Module

ICG module ensures that when a particular HSDIV is not enabled the HSDIV clock output is gated off. This is a hardware module with no software control.

6.4.5.4.1.2.5 PLL Power Down

PLLTS16FFCLAFRACF2 is disabled with MCU_PLL0_CTRL[15] PLL_EN or PLLn_CTRL[15] PLL_EN.

6.4.5.4.1.2.6 PLL Calibration

PLLTS16FFCLAFRACF2 has calibration feature. The calibration settings are done via <PLL_Name>_CAL_CTRL register. The calibration status can be monitored by reading

Copyright © 2024 Texas Instruments Incorporated

<PLL_Name>_CAL_STAT register. For more information about device-specific information about calibration feature, see Table 6-35.

6.4.5.4.2 PLL Spread Spectrum Modulation Module

Spread Spectrum Modulation (SSMOD) modules on the device reduces Electro Magnetic Interference (EMI). It is a fully-digital circuit, used to modulate the frequency of the selected fractional PLLs. Programming options include selection of center spread or down spread, modulation depth, and modulation shape. The default modulation profile is triangular.

All PLLs in this family of device have SSMOD module.

SSMOD in the PLL is performed by changing the feedback divider (FRAC and FB_DIV) in a triangular pattern. This varies the frequency of the output clock in a triangular pattern. The frequency of this pattern is the modulation frequency (f_m). It is programmed as a ratio of the CLKIN/4.

Figure 6-43 shows a diagram of the spreading generation block.

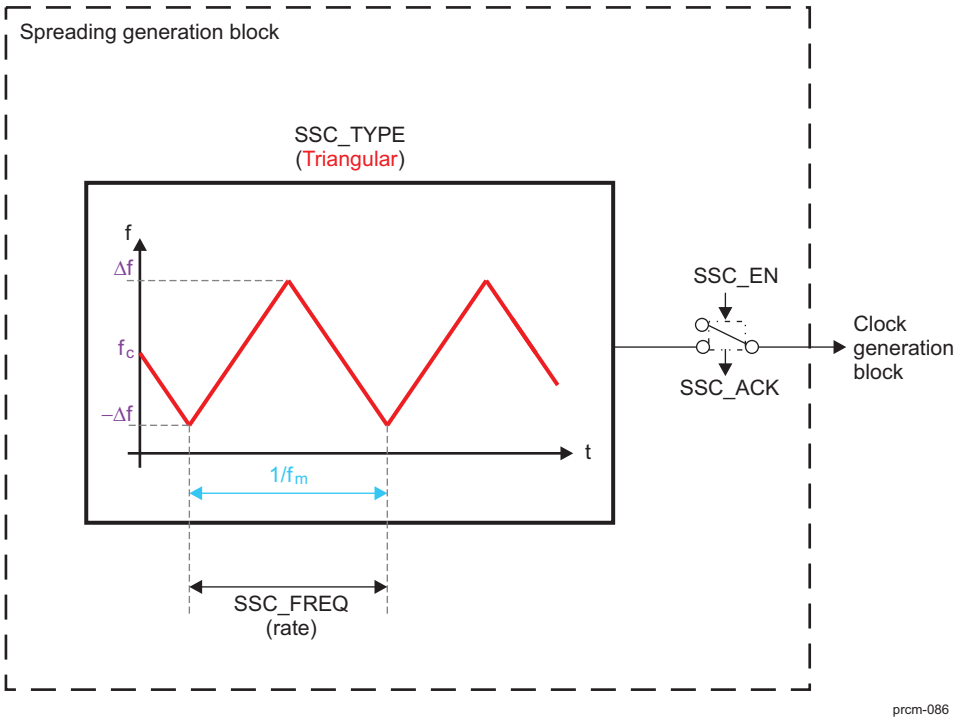


Figure 6-43. Spreading Generation Block Diagram

Note

Δf is the deviation from the center frequency. The total spreading deviation is equal to twice Δf. The peak (ΔM) or the amplitude of the triangular/square pattern as a percent of M would be equal to the percent of the frequency spread (Δf), $\Delta M/M = \Delta f/f_c$.

f_c is the original output clock frequency.

f_m is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal to add some controlled deviation to the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces EMI. SSMOD_DOWNSPREAD can control the position of the generated signal. It is controlled by the <PLL_name>_CTRL[4] DOWNSPREAD_EN

Copyright © 2024 Texas Instruments Incorporated

bit of the corresponding registers. If the DOWNSPREAD_EN bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0.

The value of SSMOD_FREQ controls the rate of the generated signal. It can be programmed as a ratio of the reference clock: f_{ref} / 4. The value that must be programmed is calculated as follows:
ModFreqDivider = f_{ref} / (4 × f_m), where $f_m < f_{ref} / 70$, $f_{ref} = f_{inp} / (1+N)$, and f_{inp} is the input clock for the PLL.

6.4.5.4.2.1 Definition of SSMOD

The aim of the SSMOD is to add a variation to the frequency of an original clock, which spreads the generated interference over a larger band of frequencies.
In theory, SSMOD means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 MHz at one time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be spread out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.
Creating an SSMOD by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.

6.4.5.4.2.2 SSMOD Configuration

Table 6-30 describes the PLL SSMOD control bitfields. Figure 6-44 describes the connection between a SSMOD and a PLL.

Table 6-30. SSMOD related bitfields

Parameter	Register	Description
SSMOD enable control	<PLL_name>n_SS_CTRL[31](1) BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[31] BYPASS_EN)	Enable/disable the PLL SSMOD feature.
Wave table maximum address	<PLL_name>n_SS_CTRL[25-18](1) WV_TBL_MAXADDR (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[25-18] WV_TBL_MAXADDR)	Wave table maximum address. Indicates the maximum number of address bits used to access the externalwave table. These bits are not used if <PLL_name>n_SS_CTRL[0] WAVE_SEL = 0
Type of spread	<PLL_name>n_SS_CTRL[4](1) DOWNSPREAD_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[4] DOWNSPREAD_EN)	Selects center spread or down spread clock variance
Wave table selection	<PLL_name>n_SS_CTRL[0] (1) WAVE_SEL (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[0] WAVE_SEL)	Wave pattern select External wave table should only be selected
Modulation dvider	<PLL_name>n_SS_SPREAD[19-16] (1) MOD_DIV (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[19-16] MOD_DIV)	Input clock divider. This divider sets the modulation frequency.
Spread Depth	<PLL_name>n_SS_SPREAD[4-0] (1) SPREAD (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[4-0] SPREAD)	Sets the spread modulation depth.

(1) n = 0 for MCU domain and n = 0 - 2, 8, 12, 15, 16 and 17 for MAIN domain

Table 6-34. Clock Output Parameter for PLLTS16FFCLAFRACF2 Type (continued)

Clock Output/Divider	Parameter Name	Control/Status Bit Field
Enable fractional noise canceling DAC	Control	<PLL_name>_CTRL[0] DAC_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[0] DAC_EN)

(1) j is the number of HSDIV for the current PLL.

6.4.5.5.4 Calibration Related Bitfields

Table 6-35 lists the calibration related bitfields/bits.

Table 6-35. Recalibration Feature Parameters

Recalibration feture	Parameter Name	Control/Status Bit Field
Calibration enable to actively adjust for input skew	Control	<PLL_name>_CAL_CTRL[31] CAL_EN (For example, PLL12 - PLL12_CAL_CTRL[31] CAL_EN)
Fast calibration enabled	Control	<PLL_name>_CAL_CTRL[20] FAST_CAL (For example, PLL12 - PLL12_CAL_CTRL[20] FAST_CAL)
Calibration loop programmable counter	Control	<PLL_name>_CAL_CTRL[18-16] CAL_CNT (For example, PLL12 - PLL12_CAL_CTRL[18-16] CAL_CNT)
Calibration bypass	Control	<PLL_name>_CAL_CTRL[15] CAL_BYP (For example, PLL12 - PLL12_CAL_CTRL[15] CAL_BYP)
Calibration input	Control	<PLL_name>_CAL_CTRL[11-0] CAL_IN (For example, PLL12 - PLL12_CAL_CTRL[11-0] CAL_IN)
Output of the calibration block	Status	<PLL_name>_CAL_STAT[11-0] CAL_OUT (For example, PLL12 - PLL12_CAL_STAT[11-0] CAL_OUT)

6.4.5.6 PLL Controller (PLLCTRL)

The PLLCTRL manages clock alignment of CBASS clocks to the peripherals in Main and MCU domains. In addition PLLCTRL is also responsible for controlling reset propagation through the chip and providing DFT hooks for testability. Two PLL Controllers are implemented in the device - PLLCTRL0 and MCU_PLLCTRL0. They are respectively related to PLL0 and MCU_PLL0.

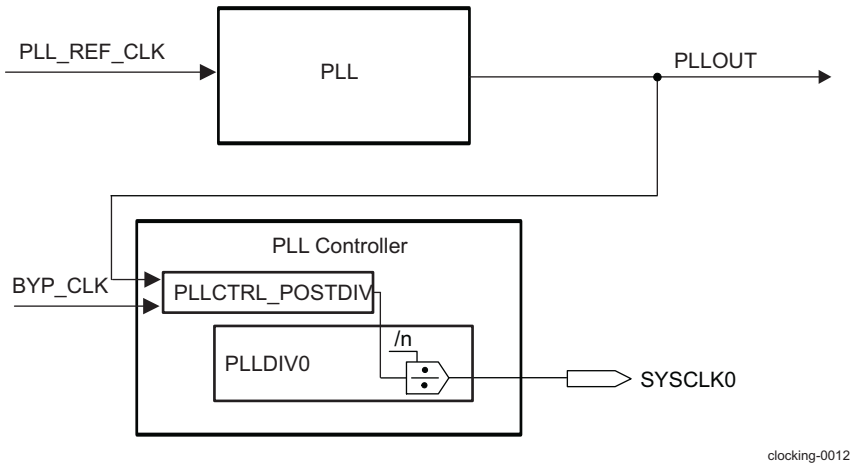

Figure 6-45. PLL Controller

Copyright © 2024 Texas Instruments Incorporated

Note

PLLCTRL_POSTDIV is not supported in this family of devices.

Note

The PLL Controllers registers can be accessed by any controller in the device.

A SYSCLK0 clock out of a PLLCTRL is the only synchronous clock in that domain. That means - MCU_SYSCLK0 out of MCU_PLLCTRL is the synchronous CBASS clock in MCU domain and SYSCLK0 out of Main PLLCTRL is the synchronous CBASS clock in Main domain.

6.4.5.7 PLL, PLLCTRL, and HSDIV Controllers Programming Guide

6.4.5.7.1 PLL Initialization

6.4.5.7.1.1 Kick Protection Mechanism

Note

PLL configuration registers are write-protected at power-up. Software must first un-lock the PLLn_LOCKKEY0 and PLLn_LOCKKEY1 registers prior to writing to any chip-level registers.

The un-lock process shall follow the steps:

1. Write value 0x68EF3490 to PLLn_LOCKKEY0 register.
2. Write value 0xD172BC5A to PLLn_LOCKKEY1 register.

After these two steps a write access to the PLL registers is allowed. Writing any other data value to either of these two registers locks the kicker mechanism and blocks any writes to the PLL registers.

Note

In order to ensure that all PLL registers are write protected, software must always re-lock the kicker mechanism after completing the register writes.

6.4.5.7.1.2 PLLCTRL Initialization

Note

For validated set of parameters that can be programmed to PLLs, please refer to the device-specific Datasheet.

Initially, the device powers up in PLL bypass mode. The bypass mux is a glitch free mux and is located outside the PLL module. BYPASS_EN bit controls the bypass mux section. During Power-up, the bypass mux defaults to select FREF clock (PLL clock bypass mode).

The following shows the PLL initialization sequence.

1. Wait until supplies are stable and PORz is de-asserted. By this time the reference clock source must be up and running.
2. Default controls settings:
   - By default PLL_EN signal is Low provided by <PLL_name>_CTRL register default state. This signal behaves like a reset control to the PLL.
   - By default INTL_BYP_EN signal is low provided by <PLL_name>_CTRL register default state.
   - By default BYPASS_EN signal is high provided by PLL MMR CTRL default state. PLL clock will be bypassed externally by a glitch free mux. The output of the mux will be the reference clock FREF.
   - LOCK output of PLL will be Low.

Copyright © 2024 Texas Instruments Incorporated

3. Program the PLL to a valid setting that runs the VCO within the specified range. The following bits/bitfields must be programmed appropriately by software: DSM_EN, DAC_EN, CLK_POSTDIV_EN, CLK_4PH_EN, REF_DIV[5-0], FB_DIV[11-0], FB_DIV_FRAC[23-0], POST_DIV1[2-0], POST_DIV2[2-0].
4. Wait for 1 µs to allow the PLL internal reset to complete (PLL powerdown switch pulls the loop filter voltage from rail-to-rail, which ensures the PLL will be completely powered down from any state).
5. Assert PLL_EN to a High (by writing a '1' into PLL_EN bit in <PLL_name>_CTRL register).
6. Wait for PLL Lock output to go high. Software can read the LOCK bit in <PLL_name>_STATS register to check if PLL has locked.
7. De-assert BYPASS_EN signal to a Low by writing 0 into BYPASS_EN bit in <PLL_name>_CTRL register.
8. Glitch free mux safely switches to the PLL clock output.

Note

In the case of brown out (supply dips below datasheet minimum) or loss of the reference clock, the state of the PLL will be undetermined. A full reset sequence should be initiated.

Changing PLL setting: During normal operation, before changing PLL settings, the PLL clock must be bypassed by setting BYPASS_EN control to a high. Then follow steps 2 to 8 from the above sequence.

6.4.5.7.1.3 PLL Programming Requirements

- A PLL VCO frequency must be set to > 1500 MHz
  - For best PLL performance, maximize VCO frequency where possible.
- A PLL must always operate in Fractional Mode (DAC_EN and DSM_EN set to ‘1’). This is true even when the FB_DIV is a integer.
- A PLL Reference clock frequency must be > 10 MHz.
- REF_DIV[5:0] must be set to “000001”.
- Calibration procedures for FRACF PLLs in integer mode or fractional mode:
  - **Programming FRACF in Integer Mode with calibration (Static or Auto Calibration)**
    - Set all the common PLL settings (PREDIV, FBDIV, …)
    - DACEN: 0
    - DSMEN = 0 (INT MODE)
    - FASTCAL=1
    - CALBYPASS=0
    - CALCNT[2:0]=2
    - CALIN[11:0]=0
    - CAL_EN=1
    - SET PLL_EN = 1
    - WAIT FOR PLL_LOCK AND CAL_LOCK GO HI
    - CAPTURE AND STORE CALCODE WHEN CAL_LOCK GOES HI IF IT WILL BE USED LATER
    - IF CAL_LOCK times out (> 2 ms) then continue
    - CAL_EN=0 (OPTIONAL, THIS WILL FREEZE CALIBRATION & INTERNAL CALCODE)
  - **Programming FRACF in Fractional Mode (with Static Calcode)**
    - Set all common PLL settings to nearest integer (PREDIV, FBDIV,...)
    - Run calibration as outlined in integer mode
    - CAPTURE AND STORE CALCODE WHEN CAL_LOCK GOES HI IF IT WILL BE USED LATER
    - IF CAL_LOCK times out (> 2 ms) then continue
    - CAL_EN=0 (THIS WILL FREEZE CALIBRATION & INTERNAL CALCODE)
    - IF CAL_LOCK timed out, keep CALBYPASS=0
    - IF CAL_LOCK IS ASSERTED AND CALCODE IS CAPTURED APPLY CALCODE TO CALIN
    - CALBYPASS=1 CALCODE IS SET BY CALIN
    - ENABLE FRACTIONAL MODE
  - **Programming FRACF in Fractional Mode (Auto-Calibration Not Allowed)**
    - Set all the common PLL settings (PREDIV, FBDIV, …)
    - DACEN=1

Copyright © 2024 Texas Instruments Incorporated

- DSMEN=1 (FRAC MODE)
- FASTCAL =X
- CALBYPASS=1 CALCODE IS SET BY CALIN
- CALCNT[2:0]=XX
- CALIN[11:0] = 0 (OR DESIRED CALCODE)
- CAL_EN = 0
- SET PLL_EN = 1
- WAIT FOR PLL_LOCK

PLL Integer mode with Calibration enabled is recommended for applications sensitive to phase noise or jitter: Examples include Refclk for SerDes, PHY, DDR etc. See individual product datasheets for specific SoC requirements. Calibration can be bypassed for digital clocks like ARM. If Calibration is bypassed, CALIN needs to be set to 0.

When Calibration is enabled, PLL Lock time will be longer since SOC needs to wait for CAL_LOCK. Applications sensitive to phase noise must wait for CAL_LOCK to go high.

6.4.5.7.2 HSDIV PLL Programming

<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 0 cleanly disables the HSDIV output clock

<PLL_Name>_HSDIV_CTRLk[6-0] HSDIV = <value> for divider

<PLL_Name>_HSDIV_CTRLk[8] SYNC_DIS = 0 insures that the divider changes occur synchronously to the internal divider of the HSDIV block.

when the clock is required,

<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 1 cleanly enables the HSDIV output clock

6.4.5.7.3 PLL Controllers Programming - Dividers PLLDIVn and GO Operation

The GO operation is required to change the divider ratios of the PLLDIVn registers. Section 6.4.5.7.3.1, *GO Operation*, discusses the GO operation. Section 6.4.5.7.3.2, *Software Steps to Modify PLLDIVn Ratios*, provides the software steps required to change the divider ratios.

6.4.5.7.3.1 GO Operation

The GO operation writes to the RATIO field in the PLLDIVn. Registers do not change the dividers' divide ratios immediately. The PLLDIV dividers change to the new RATIO rates only during a GO operation. This section discusses the GO operation and alignment of the SYSCLKs.

The PLL Controller clock align control register (ALNCTL) determines which SYSCLKs must be aligned. Before a GO operation, program ALNCTL so that the appropriate clocks are aligned during the GO operation.

A GO operation is initiated by setting the GOSET bit in PLLCMD to 1. During a GO operation:

- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL and SYS *n* bit in DCHANGE set to 1 is paused at the low edge. Then the PLL Controller restarts all these SYSCLKs simultaneously, aligned at the rising edge. When the SYSCLKs are restarted, SYSCLK *n* toggles at the rate programmed in the RATIO field in PLLDIVn.
- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL cleared and the SYS *n* bit in DCHANGE set immediately changes to the new rate programmed in the RATIO field.
- The GOSTAT bit in PLLSTAT is set throughout the duration of a GO operation.

CAUTION

To help prevent errors, all device operation must be stopped before the GO operation.

6.4.5.7.3.2 Software Steps to Modify PLLDIV Ratios

Perform the following steps to modify PLLDIV.

1. Check that the GOSTAT bit in PLLSTAT is cleared to show that no GO operation is currently in progress.

Copyright © 2024 Texas Instruments Incorporated

2. Program the RATIO field in PLLDIVn to the desired new divide-down rate. If the RATIO field changed, the PLL Controller will flag the change in the corresponding bit of DCHANGE.
3. Set the respective ALN *n* bits in ALNCTL to align any SYSCLKs after the GO operation.
4. Set the GOSET bit in PLLCMD to initiate the GO operation to change the divide values and align the SYSCLKs as programmed.
5. Read the GOSTAT bit in PLLSTAT to make sure the bit returns to 0 to indicate that the GO operation has completed.

6.4.5.7.4 Entire Sequence for Programming PLLCTRL, HSDIV, and PLL

Table 6-36 shows the entire sequence of programming PLLCTRL, HSDIV, and PLL from an unknown state to a defined non-spread-spectrum state.

Table 6-36. Programming Sequence of PLLCTRL, HSDIV, and PLL

Step	Description
Unlock PLL registers	<PLL_Name>_LOCKKEY0 (= 0x68EF3490)
	<PLL_Name>_LOCKKEY1 (= 0xD172BC5A)
If PLL0	Configure PLLCTRL block into bypass mode
	PLLCTL[0]PLLEN = 0
	PLLCTL[5] PLLENSRC = 0
Configure external bypass so that no transient clock propagates	<PLL_Name>_CTRL[31] BYPASS_EN = 1
Delay	
Disable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN =0
Delay	
Disable PLL	<PLL_Name>_CTRL[15] PLL_EN =0
Delay	
Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 1
If PLL0	Check PLLSTAT[0] GOSTAT to make sure that divider change is not currently in-progress GOSTAT should equal 0.
	Clear GOSET bit PLLCMD[0] GOSET = 0
	Configure divider in PLLCTRL to /1 PLLDIV1 = 0x8000 (enable divider and divide by 1) PLLDIV2 = 0x00 (disable divider and divide by 1)
	Set alignment control bits ALNCTL = 3
	Set GOSET bit to initiate the divider change PLLCMD[0] GOSET = 1
	Check PLLSTAT[0] GOSTAT to make sure that divider change has completed GOSTAT should equal 0.
Configure HSDIV(s) divider value	<PLL_Name>_HSDIV_CTRLk[6-0] HSDIV (=val)
Clear HSDIV(s) SYNC_DIS	<PLL_Name>_HSDIV_CTRLk[8] SYNC_DIS = 0
Delay	
Clear Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 0
Configure PLL multiplier	Integer portion of divider <PLL_Name>_FREQ_CTRL0[11-0] (=val) Fractional portion of divider <PLL_Name>_FREQ_CTRL1[23-0] (=val)
Configure PLL dividers	Reference clock divider <PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1
	Post divider 1 <PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1

Table 6-36. Programming Sequence of PLLCTRL, HSDIV, and PLL (continued)

Step	Description
	Post divider 2 <PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1
Configure “random” PLL controls	<PLL_Name>_CTRL[8] INTL_BYP_EN = 0
	<PLL_Name>_CTRL[5] CLK_4PH_EN = 0
	<PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1
	<PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1
	<PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1
	<PLL_Name>_CTRL[1] DSM_EN = 1
	<PLL_Name>_CTRL[0] DAC_EN = 1
	<PLL_Name>_SS_CTRL[31] BYPASS_EN (SSMOD) = 1
	<PLL_Name>_CTRL[4] CLK_POSTDIV_EN – if PLL has more than 5 HSDIV blocks, 1; else 0.
	<PLL_Name>_CTRL[16] BYP_ON_LOCKLOSS (= {0, 1})
Delay	
Enable PLL	<PLL_Name>_CTRL[15] PLL_EN = 1
Wait for Lock	Wait for MCU_PLL0_STAT[0] LOCK = 1
Enable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 1
Delay	
Configure external bypass to pass PLL	<PLL_Name>_CTRL[31] BYPASS_EN = 0
Delay	
If PLL0	Configure PLLCTRL block into PLL mode PLLCTL[0] PLLEN = 0
Lock PLL registers	<PLL_Name>_LOCKKEY0 (= any value)
	<PLL_Name>_LOCKKEY1 (= any value)

6.4.5.7.5 Dual Clock Comparator (DCC)

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference. Internal 12.5 MHz RC oscillator clock is used to validate HFOSC0_CLKOUT. Then HFOSC0_CLKOUT (most accurate clock) is used to validate/track all other clocks in the device. An additional use of this module is to measure the frequency of a selectable clock source, using an external input clock source of known frequency (MCU_EXT_REFCLK0, EXT_REFCLK1 pins). There is one instance of DCC module in MCU domain and seven instances of DCC modules in Main domain to monitor critical clocks. Refer to DCC chapter for details.

6.4.5.7.6 DeepSleep Clock Gating

This device supports deepsleep mode where the HFOSC0_CLK is synchronously gated during deep-sleep entry sequence. HFOSC0 Clock loss detection mux control must be disabled during Deepsleep entry mode. (CLKLOSS_SWITCH_EN must be ‘0’).

In addition, HFOSC0 can be put into Power-down mode. When exiting deep-sleep mode, HFOSC0 is powered-up, wait until clock is stabilized and disable the clock gating so clock can propagate to PLL and Wake-up domain. This function is handled by Deep-sleep Hardware logic in Wake-up Domain.

Copyright © 2024 Texas Instruments Incorporated

6.4.5.7.6.1 Software responsibility of clock settings during deeplseep mode

- Before going into deepsleep mode, software must ensure to configure the clock mux controls of modules in MCU domain such that when it resumes from sleep mode these modules will have a functional clock when MCU domain reset is de-asserted. Examples of such modules are: TIMER, WDT/RTI, SPI, MCAN and UART. This is a very important requirement to ensure a proper reset of MCU domain modules coming out of deeplseep mode.
- For modules in Wake-up domain, during deepsleep resume, DM/Pulsar must ensure to first enable the functional clocks before accessing the modules in wake-up domain. This requirement is also applicable during normal mode of operation.

7.1 Arm Cortex-A53 Subsystem (A53SS)

This section describes the Arm® Cortex®-A53 Subsystem (A53SS) in the device.

Copyright © 2024 Texas Instruments Incorporated

7.1.1 A53SS Overview

7.1.1.1 A53SS Introduction

The SoC implements one cluster of quad-core Arm® Cortex® A53 MPCore™, with 32KB L1 instruction, 32KB L1 data, per core and 512KB L2 shared cache.

The Cortex®-A53 cores are general-purpose processors that can be used for running customer applications.

Note

Notes on references used in this document:
- A53SS is also referred to as Arm® CorePac.
- Cortex®-A53 is often shortened to A53.

The A53SS is built around the Cortex®-A53 MPCore™ (Arm® A53 Cluster), which is provided by Arm and configured by TI. It is based on the symmetric multiprocessor (SMP) architecture, and thus it delivers high performance and optimal power management, debug and emulation capabilities.

The A53 processor is a multi-issue out-of-order superscalar execution engine with integrated L1 Instruction and Data Caches, compatible with Arm®v8-A architecture. It delivers significantly more performance than its predecessors at a higher level of power efficiency.

The Arm®v8-A architecture brings a number of new features. These include 64-bit data processing, extended virtual addressing and 64-bit general purpose registers. The A53 processor is Arm's first Arm®v8-A processor aimed at providing power-efficient 64-bit processing. It features an in-order, 8-stage, dual-issue pipeline, and improved integer, Arm® Neon™, Floating-Point Unit (FPU) and memory performance.

The A53 CPU supports two execution states: AArch32 and AArch64. The AArch64 state gives the A53 CPU its ability to execute 64-bit applications, while the AArch32 state allows the processor to execute existing Arm®v7-A applications.

7.1.1.2 A53SS Features

The A53SS module supports the following features:

- Quad Core A53 Cluster
  - Full Arm®v8-A Architecture Compliant
    - AArch32 and AArch64 Execution States
    - All exception levels EL0-3
    - A32 Instruction Set (Previously Arm instruction set)
    - T32 instruction set (Previously Thumb instruction set)
    - A64 Instruction Set
  - Data Coherency within Cluster (L1/L2 caches)
  - Advanced SIMD and Floating Point Extensions (Arm® Neon™)
  - Armv8 Cryptography Extensions
  - Arm GICv3 architecture
  - In-order pipeline with symmetric dual-issue of most instructions
  - Harvard L1 with system MMU
    - 32 KB Instruction Cache
    - 32 KB Data Cache
  - 512KB Shared L2 Cache
  - Generic Timer(s)
  - Debug
- 128-Bit VBUSM Initiator Interfaces (for axi_r and axi_r channels)
- 128-Bit VBUSM Target Interface (for Accelerator Coherency Port)
- 64-bit Grey-coded system input time
- 48-bit Grey-coded debug input time

Copyright © 2024 Texas Instruments Incorporated

- 48-bit Grey-coded debug input time
- Integrated PBIST controller with BISOR

Note

Some features may not be available. See *Module Integration* for more information.

Copyright © 2024 Texas Instruments Incorporated

7.1.2 A53SS Functional Description

7.1.2.1 A53SS Block Diagram

7.1.2.2 Arm Cortex-A53 Cluster

The Arm Cortex-A53 Cluster is provided by Arm and configured by TI. Table 7-1 summarizes the configuration of the Arm Cortex-A53 Cluster on this SoC.

Table 7-1. Arm A53 Cluster Configuration

Parameter	Value
Core Type	A53
Core Revision	r0p4
Number of Cores	4
Bus Width	256
L1 Instruction Cache Size	32K
L1 Data Cache Size	32K
L2 Cache Size	512K
SCU-L2 Cache Protection	Included
Advanced SIMD and Floating Point Extension	Included
Cryptography Extension	Included
CPU Cache Protection	Included
AMBA5 CHI or AMBA4 ACE Interface	AMBA4 ACE (configured for AXI using tie-offs)
Accelerator Coherency Port (ACP)	Included
V7 or v8 Debug Memory Map	v8

Note

For a brief list of features supported by the Arm Cortex-A53 Cluster, see A53SS Features.

For detailed description of the Arm A53 Cluster, see the *ARM®Cortex®-A53 MPCore Processor Technical Reference Manual*.

7.1.2.3 A53SS Interfaces and Async Bridges

The A53SS has the following main interfaces:

- 64-bit graycoded system input time
  - Graycode value provided by Global Timebase Counter (GTC)
  - Dedicated decoder (64-bit input) for graycode-to-binary conversion
- 48-bit graycoded debug input time
  - Graycode value provided by GTC
  - Dedicated decoder (48-bit input) for graycode-to-binary conversion
- 32-bit VBUSP target interface for debug
  - Supported by VBUSP2APB Bridge, which performs VBUSP-to-APB conversion (for controlling the Arm A53 Cluster internal debug logic)
- 32-bit ATB output port for debug/trace
  - Supported by ATB Bridge, which performs clock and voltage level conversion on the combined ATB interface
  - Connected to the Debug Subsystem
- Cross Trigger Interface (CTI) for debug
  - Connected to the Debug Subsystem
- Interface(s) with Arm GIC-500 Interrupt Controller

Copyright © 2024 Texas Instruments Incorporated

  - Supported by GIC AXI Streaming Bridge, which performs clock and voltage level conversion on the AXI streaming protocol
  - Interrupts (PPIs) from Arm A53 Cluster to GIC-500
  - Interrupts (IRQ, FIQ, VIRQ, VFIQ) from GIC-500 to Arm A53 Cluster
- Power/clock interface(s)
  - Dedicated PLL for each Arm A53 Cluster
  - Dedicated LPSC for each Arm A53 Cluster, and also for each A53 core

7.1.2.4 A53SS Interrupts

7.1.2.4.1 A53SS Interrupt Inputs

The A53 CPU recieves interrupts at its inputs (IRQ, FIQ, VIRQ, VFIQ) via the dedicated Arm GIC-500 Interrupt Controller, which resides at the SoC level (MAIN Domain) and is integrated inside the GIC0 Subsystem. The GIC-500 supports all four A53 cores in the system.

The GIC-500 is compliant to the Arm GICv3 standard and supports four types of interrupts:

- *Software Generated Interrupts (SGI)*
  - There are 16 SGIs (ID0-ID15)
  - These are inter-processor interrupts
- *Private Peripheral Interrupts (PPI)*
  - There are 16 PPIs (ID16-ID31)
  - These are wired interrupts dedicated to a specific CPU
  - Many are reserved to specific functions via convention
- *Shared Peripheral Interrupts (SPIs)*
  - There are 256 SPIs (ID32-ID288)
  - These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC500
- *Locality-Specific Peripheral Interrupts (LPI)*
  - There are 57,344 LPIs
  - These interrupts are used for message-based interrupts from a peripheral

The mapping of PPIs and SPIs to the GIC-500 interrupt inputs can be found in *Interrupts*.

Note

For a brief list of features supported by the GIC-500 module, see the *Interrupts* chapter.

For detailed description of the GIC-500 module, see the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

7.1.2.4.2 A53SS Interrupt Outputs

A53SS Interrupt Outputs lists the interrupts generated by the A53SS.

Table 7-2. A53SS Interrupt Outputs

Interrupt Name (TI)[1]	Interrupt Name (Arm)	Interrupt Description
A53 Core Interrupts (PPIs)[2]		
A53_COREy_VCPUMNTIRQ	VCPUMNTIRQn	This interrupt indicates that a Virtual CPU Interface on the corresponding core needs serviced. This interrupt is serviced by software switching to the virtual CPU and finding what specific service needs done.
A53_COREy_CNTHPIRQ	CNTHPIRQn	This interrupt indicates a physical timer event at the EL2 (Hypervisor) exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL2 and service accordingly.

Copyright © 2024 Texas Instruments Incorporated

Table 7-2. A53SS Interrupt Outputs (continued)

Interrupt Name (TI)(1)	Interrupt Name (Arm)	Interrupt Description
A53_COREy_CNTPNSIRQ	CNTPNSIRQn	This interrupt indicates a physical timer event at the EL1 Non-Secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 Non-Secure and service accordingly.
A53_COREy_CNTPSIRQ	CNTPSIRQn	This interrupt indicates a physical timer event at the EL1 Secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 Secure and service accordingly.
A53_COREy_CNTVIRQ	CNTVIRQn	This interrupt indicates a Virtual timer event. Service of this interrupt is dependent on what the timer was set for. Software should take exception and service accordingly.
A53_COREy_PMUIRQ	PMUIRQn	This interrupt is generated by the Performance Monitor Unit (PMU). The PMU can generate an interrupt based on several conditions, depending on programming. Software should take exception and query the PMU as to the cause of the interrupt, and act accordingly.
A53_COREy_DCCIRQ	COMMIRQn	Communications Channel receive or transmit interrupt
A53_COREy_CTIIRQ	CTIIRQn	Cross Trigger Interface interrupt

(1) In this column, *y* is the A53 Core index (0 or 1)
(2) These are 'per core' interrupts

Note

The mapping of these interrupts in the system is summarized in *A53SS Integration*, and can also be found in *Interrupts*.

For more detailed description of these interrupts and their handling, see the *Arm® Cortex®-A53 MPCore Processor Technical Reference Manual*.

7.1.2.5 A53SS Power Management and Clocking

7.1.2.5.1 A53SS Power Management

Each Arm A53 Cluster and each A53 CPU reside in a separate power domain, as follows:

There is a dedicated Local Power Sleep Controller (LPSC) for each Arm A53 Cluster, and for each A53 core, as well. The LPSC assignment is as follows:

For more details on these LPSCs, including power-up/down sequences, see *Power*.

7.1.2.5.2 A53SS Clocking

There is a dedicated PLL for each Arm A53 Cluster. The PLL assignment is as follows:

- PLL8 (ARM0 PLL): Dedicated for Arm A53 Cluster 0

For more details on these PLLs, see *Clocking*.

7.1.2.6 A53SS Debug

The A53SS supports the standard Arm debug architecture. Details on Arm debug can be found in the *On-chip Debug* chapter and the relevant Arm specifications.

7.1.2.7 A53SS Global and Debug Timestamps

The A53SS has two timebase input interfaces:

- 64-bit global timestamp: Used for synchronizing the Arm internal timers (via the ARM CNTVALUEB [63:0] bus)
- 48-bit debug timestamp: Can be embedded in Arm trace streams at periodic and strategic locations, allowing the temporal relationship of different trace sources to be determined

Copyright © 2024 Texas Instruments Incorporated

Both of them are fed by the Global Timebase Counter (GTC), which provides a 64-bit graycode value. The A53SS includes two graycode decoders (for global time and debug time, respectively), which take the asynchronous graycoded times, synchronize them to the appropriate clock, and convert them to binary time, as required by Arm.

Note

Both graycode decoders are 64-bit but the one dedicated to debug time has a 48-bit input (the upper 16 bits are tied to 0).

For more details on the GTC, see *Global Timebase Counter (GTC)*.

7.1.2.8 A53SS Watchdog

The A53SS does not have an integrated watchdog timer. Instead, this feature is provided externally by the Real Time Interrupt Module (RTI) module, which implements a windowed watchdog timer capable of issuing warm reset to the SoC, when necessary.

For more details on the RTI windowed watchdog feature, see *Real Time Interrupt Module (RTI/WWDT)*.

7.1.2.9 A53SS Functional Safety - ECC Error Injection Support

In the quad A53 CBA subsystem, there are five ECC aggregators – one for each core and one for the corepac level. Debug domain is not safety critical.

No CBASS/Bridge interconnect safety is supported. Only RAM safety is supported.

The following A53SS ECC Aggregator instances are instantiated:

- A53SS0_ECC_AGGR0: ECC Aggregator for Arm A53 Cluster 0, Core 0
- A53SS0_ECC_AGGR1: ECC Aggregator for Arm A53 Cluster 0, Core 1
- A53SS0_ECC_AGGR2: ECC Aggregator for Arm A53 Cluster 0, Core 2
- A53SS0_ECC_AGGR3: ECC Aggregator for Arm A53 Cluster 0, Core 3
- A53SS0_ECC_AGGR_COREPAC: ECC Aggregator for Arm A53 Cluster 0

7.1.2.9.1 A53 ECC Aggregators During Low Power States

- When a cpu core is in WFI/WFE, the corresponding core ECC Aggregator MMR regions is not accessible and will return error status.
- Similarly when L2 is in WFI, the corepac ECC Aggregator MMR region is not accessible and will return error status.

7.1.2.9.2 Auto-initialization of Memories

All A53 L1 and L2 memory initialization is handled by the Arm core. The TI ECC aggregator is used in inject-only mode and this cannot be used for initialization. The Arm CPU will initialize the cache memories after reset.

There are no other memories in the A53 subsystem beside the cache memories

7.1.2.9.3 A53 SRAM Safety

The Arm A53 Cluster natively supports ECC/parity protection on A53 SRAMs and error injection on few memories. The A53SS adds error injection capability on all internal SRAM. This is a valuable TI addition to the Arm native implementation.

Table 7-3. A53 SRAM Safety Support

RAM	A53 Error Injection Support	TI Error Injection Support
L1 I-Cache Data	No	Single error injection
L1 I-Cache Tag	No	Single error injection
L1 D-Cache Data	Double error injection	Single and double error injection
L1 D-Cache Tag	No	Single error injection
L1 Data Dirty	No	Single error injection

Copyright © 2024 Texas Instruments Incorporated

Table 7-3. A53 SRAM Safety Support (continued)

RAM	A53 Error Injection Support	TI Error Injection Support
TLB RAM	No	Single error injection
SCU Duplicate Tag	No	Single and double error injection
L2 Tag RAM	Double error injection	Single and double error injection
L2 Data RAM	Double error injection	Single and double error injection

The ECC Aggregator for the cores stimulates errors in the following RAMs:

- L1 I-Cache Data RAM
- L1 I-Cache Tag RAM
- L1 D-Cache Data RAM
- L1 D-Cache Tag RAM
- L1 D-Cache Dirty RAM
- TLB RAM
- L1 SCU L1-D Duplicate Tag RAM

The ECC Aggregator for the L2 cache stimulates errors in the following RAMs:

- L2 Data RAM
- L2 Tag RAM

7.1.2.9.4 A53 SRAM ECC Aggregator Configurations

There are several schemas of memory protection employed inside of the processors. The tables below describe the schema and arrangement. This describes what bits are protected, how they are protected, the behavior when an error is detected and what bits can be disturbed for ECC testing purposes. This also lists the RAMID associated with each memory to the corresponding ECC Aggregator.

The key for the protection schemes is as follows:

- Parity – Parity Bit(s) to protect data
- ECC – Error Correction Code to protect Data
- SED – Single Error Detection
- SECDED – Single Error Correction, Double Error Detection
- SEDSEC – Single Error Detection, Single Error Correction

Table 7-4. CPU Memories Safety Details

Memory	Protection	RAM Arrangement	CPU (Core ECC Aggr) Rams Ram ID	Notes
L1 I-Cache Data	Parity SED	41 – Parity for 40:21 40:21 – Instruction 20 – Parity for 19:0 19:0 – Instruction	0-3	Error detection results in both lines being invalidated then refetched from L2 or memory
L1 I-Cache Tag	Parity SED	31 – Parity for 30:0 30:0 – Data	4-5	Error detection results in both lines being invalidated, then line refetched from L2 or memory
L1 D-cache Data	ECC SECDED	38:32 – ECC 31:0 – Data	6-13	Error results in line being cleaned and invalidated from L1 with single bit errors corrected as part of eviction. Line refetched from L2 or memory
L1 D-Cache Tag	Parity SED	30 – Parity for 29:0 29:0 – Tag	14-17	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Error results in line cleaned and invalidated from L1. SCU duplicate tags are used to get the correct address. Line refetched from L2 or memory

Copyright © 2024 Texas Instruments Incorporated

Table 7-4. CPU Memories Safety Details (continued)

Memory	Protection	RAM Arrangement	CPU (Core ECC Aggr) Rams Ram ID	Notes
L1 D-cache Dirty	Parity SEDSEC	11:10 – Way 1/3 Dirty copy 2 and 1. Parity for 4 9:8 – Way 0/2 Dirty copy 2 and 1. Parity for 0 7 – Way 1/3 Outer Allocation Hint 6 – Way 1/3 Age 5:4 – Way 1/3 Partial MOESI 3 – Way 0/2 Outer Allocation Hint 2 – Way 0/2 Age 1:0 – Way 0/2 Partial MOESI	18	Error results in line cleaned and invalidated from L1 with single bit errors corrected as part of the eviction. Only dirty bit is protected. Other bits are just performance hints
TLB	Parity SED	116 – parity for 113:62 115 – Parity for 61:31 114 – Parity for 30:0 113:62 – Page Attributes 61:31 – Entry Identifiers 30:0 – Address	19-22	Error detection results in entry invalidated, new pagewalk to refetch.
SCU L1 Duplicate Tag	ECC SECDED	37:31 - ECC for 30:0 30:0 - Duplicate Tag	23-26 (accessed by each Core's ecc_aggr)	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Corretable Error – Tag rewritten with correct value, access retried Uncorrectable Error – Tag is invalidated

Table 7-5. L2 Memories Safety Details

Memory	Protection	RAM Arrangement	RAM_ID (L2 Cache RAMs)	Notes
L2 Tag	ECC SECDED	37:31 – ECC for 30:0 30:0 - Tag	0-15	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Corretable Error – Tag rewritten with correct value, access retried. Uncorrectable Error – Tag is invalidated
L2 Victim	None	–	–	Performance Hint Only – Error has no functional impact
L2 Data	ECC SECDED	71:64 – ECC for 63:0 63:0 – Data	16-23	Error results in Data corrected inline, access may stall for 1-2 cycles. After correction, line might be evicted
Branch Predictor	None	–	–	Performance Hint Only – Error has no functional impact

7.1.2.10 A53SS Boot

For A53SS boot sequence and any other A53SS boot details, see *Control Module (CTRL_MMR)*.

7.1.2.11 A53SS Interprocessor Communication

The Arm A53 core(s) can communicate with other device cores (R5FSS, PRUSS PRU, DMSC M3) by supporting interrupt generation to and from these cores. The interprocessor communication (IPC) interrupts are assigned in the corresponding BOOTCFG0 memory-mapped registers (MMRs) called IPC_SETx / IPC_CLRx. For more information, see *Control Module (CTRL_MMR)*.

7.2 Device Manager Cortex R5F Subsystem (WKUP_R5FSS)

This chapter describes the Arm Cortex R5F real-time microcontroller unit subsystem (WKUP_R5FSS) in the device.

7.2.1 WKUP_R5FSS Overview

The WKUP_R5FSS is a single-core implementation of the Arm® Cortex®-R5F processor that acts as the Device Manager responsible for boot, resource management, and power management functions. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor apply to the Cortex-R5F processor by default.

There is one WKUP_R5FSS subsystem in the device. Table 7-6 shows WKUP_R5FSS allocation across device domains.

Table 7-6. R5FSS Allocation Across Device Domains

Module Instance	Domain		
	MCU	MAIN	WKUP
WKUP_R5FSS	–	–	✓

7.2.1.1 WKUP_R5FSS Features

The WKUP_R5FSS supports the following features:

- Single-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - L1 memory system
    - 32KB instruction cache
      - 4x8KB ways
      - SECDED ECC protected per 64 bits
    - 32KB data cache
      - 4x8KB ways
      - SECDED ECC protected per 32 bits
    - 64KB tightly-coupled memory (TCM)
      - SECDED ECC protected per 32 bits
      - TCM hard error cache Implemented in CPU
      - Readable/writable from system
      - TCMs initialized (to 0's) at reset
      - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
        - 32KB TCMA (ATCM)
        - 16KB TCMB0 (B0TCM)
        - 16KB TCMB1 (B1TCM)
  - Low interrupt latency with restartable instructions
  - Non-maskable interrupt (NMI)
  - Full-precision floating point (VFPv3)
  - 16 region memory protection unit (MPU)
  - 8 breakpoints

Copyright © 2024 Texas Instruments Incorporated

  - 8 watchpoints
  - Dynamic branch prediction with global history buffer and 4-entry return stack
  - CoreSight debug access port (DAP)
  - CoreSight embedded trace macrocell (ETM-R5) interface
  - Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses
  - 64-bit VBUSM target for TCM access
    - Also allows access to cache for debug purposes
  - 32-bit VBUSP initiator for peripheral access
  - 32-bit VBUSP target configuration port
  - 32-bit VBUSP target debug port
    - Allows access to all WKUP_R5FSS internal debug logic
  - ECC/Parity support on all internal SoC bus interfaces
  - ECC/Parity support on internal SoC bus bridges
- Synchronous clock domain crossing on all interfaces
  - Interfaces can run at an integer multiple of the core frequency
- 32-bit to 36-bit region-based address translation (RAT) on memory access initiators
  - 4 regions
    - Base address + size
    - Must be size aligned
- Integrated vectored interrupt manager (VIM)
  - 256 interrupts
    - Each interrupt programmable as either IRQ or FIQ
    - Each interrupt has a programmable enable mask
    - Each interrupt has a programmable 4-bit priority
  - Priority interrupt supported
  - Vectored interrupt interface
    - Compatible with R5F VIC port
    - Programmable 32-bit vector address per interrupt
      - Address is SECDED error protected
      - Default vector addresses provided on DED
    - Software interrupt generation
- Integrated ECC aggregators
  - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
  - One ECC aggregator to cover all RAMs and caches
- Standard Arm CoreSight debug and trace architecture at the R5FSS level
  - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
  - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
  - From ROM only

See Section 7.2.2 for a functional block diagram and more details on the WKUP_R5FSS.

Note

Some features may not be available. See *Module Integration* for more information.

7.2.2 WKUP_R5FSS Functional Description

7.2.2.1 WKUP_R5FSS Block Diagram

Figure 7-2 shows the WKUP_R5FSS block diagram.

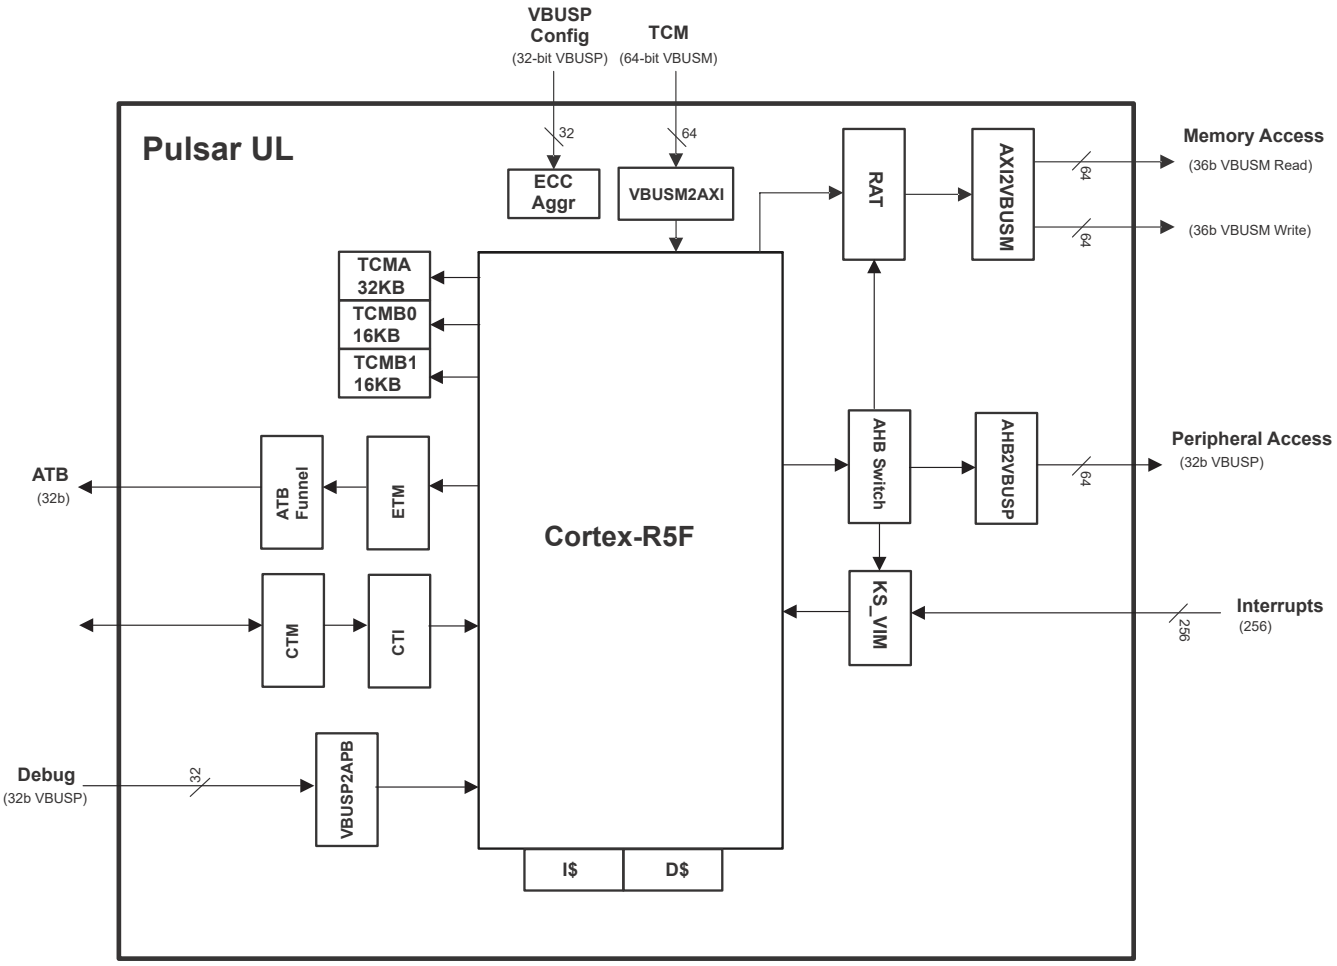

Figure 7-2. WKUP_R5FSS Block Diagram

7.2.2.2 WKUP_R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile.

For a brief list of features supported by the R5F processor in this device, see Section 7.2.1.1. For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

7.2.2.2.1 L1 Caches

The R5F has a Harvard cache architrecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

7.2.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions

Copyright © 2024 Texas Instruments Incorporated

that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM target interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM target has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPUn_INITRAMA and CPUn_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPUn_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000_0000 and the initial address of BTCM is 20'h41010. If the CPUn_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000_0000 and the initial base address of ATCM is 20'h41010.

Note

This base address of 0x41010 for ATCM/BTCM based on the CPUn_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM target interface regions, as defined in Section 7.2.2.3.2. The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See Section 7.2.2.11 for details on TCM booting.

7.2.2.2.3 WKUP_R5FSS Special Signals

Table 7-7 lists some WKUP_R5FSS features associated with special signals.

Table 7-7. WKUP_R5FSS Special Features

Feature	Comment
Cluster affinity group ID	R5F Cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
CPUn execution halt when coming out of reset (CPUn_HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPUn exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPUn VIM base address	0x2FFF_0000
CPUn RAT base address	0x2FFE_0000
CPUn RAT accesses ID	0x4 (CPU0)
CPUn ATCM enable at reset (CPUn_INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state

Copyright © 2024 Texas Instruments Incorporated

Table 7-7. WKUP_R5FSS Special Features (continued)

Feature	Comment
CPUn BTCM enable at reset (CPUn_INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPUn A/BTCM reset base address indicator (CPUn_LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPUn non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPUn VBUSM peripheral port enabled at reset	Enabled
CPUn VBUSP peripheral port enable at reset	Enabled
CPUn VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPUn VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPUn VBUSM normal peripheral port base address	Not used
CPUn VBUSM normal peripheral port size	Not used
CPUn VBUSM virtual peripheral port base address	Not used
CPUn VBUSM virtual peripheral port size	Not used
CPUn clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPUn WFI state	Status logged into MAIN_SEC_MMR register bit
CPUn WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

7.2.2.3 WKUP_R5FSS Interfaces

7.2.2.3.1 Initiator Interfaces

The WKUP_R5FSS has several initiator interfaces:

- 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSP initiator for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

7.2.2.3.2 Target Interfaces

The WKUP_R5FSS has several target interfaces that define its internal memory space:

- 32-bit VBUSP configuration target
  - Region [0]: ECC aggregator block
- 64-bit TCM target
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug target
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM target interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM target interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

Copyright © 2024 Texas Instruments Incorporated

In addition to the target interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

7.2.2.4 WKUP_R5FSS Power, Clocking and Reset

7.2.2.4.1 WKUP_R5FSS Power

The following WKUP_R5FSS power considerations should be noted:

- WKUP_R5FSS has a single power domain for all its internal logic

For more details on WKUP_R5FSS power management, including power-up and power-down sequences, see *Power*.

7.2.2.4.2 WKUP_R5FSS Clocking

The WKUP_R5FSS has four clock inputs:

- CPU0_CLK: This is the clock for CPU0 logic
- CPU0_ICLK: This is the clock for CPU0 interfaces

CPU0_CLK is the clock for all of the internal CPU logic, while CPU0_ICLK is the clock for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic).

The interface clock is an integer ratio of the CPU clock. The exact ratio for this device is 1:1.

7.2.2.4.3 WKUP_R5FSS Reset

The R5FSS has two reset inputs:

- CPU0_RST: This is the reset for the non-debug logic of CPU0
- CPU0_DBG_RST: This resets the CPU0 debug logic, excluding the APB interface

In addition to the reset signals, there is one halt signal:

- CPU0_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

7.2.2.5 WKUP_R5FSS Vectored Interrupt Manager (VIM)

7.2.2.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU. It can be used in either split or single-core configuration.

The VIM module supports the following features:

- 256 interrupt inputs for the R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS_VIM_PRI_INT_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS_VIM_INTR_EN_SET_j register
  - Interrupt disable is done via the R5FSS_VIM_INTR_EN_CLR_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS_VIM_INTMAP_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS_VIM_VEC_INT_j register
  - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port

Copyright © 2024 Texas Instruments Incorporated

- Default vector provided when a double-bit error is detected
- Software interrupt generation

7.2.2.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the R5F core can be found in *Interrupt Sources*.

7.2.2.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- *CoreN_IRQn*: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS_VIM_INTMAP_j register) and is enabled (via the R5FSS_VIM_INTR_EN_SET_j register), then it will cause an IRQ to assert
- *CoreN_FIQn*: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

7.2.2.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS_VIM_VEC_INT_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-3 shows the VIM RAM interrupt vector map.

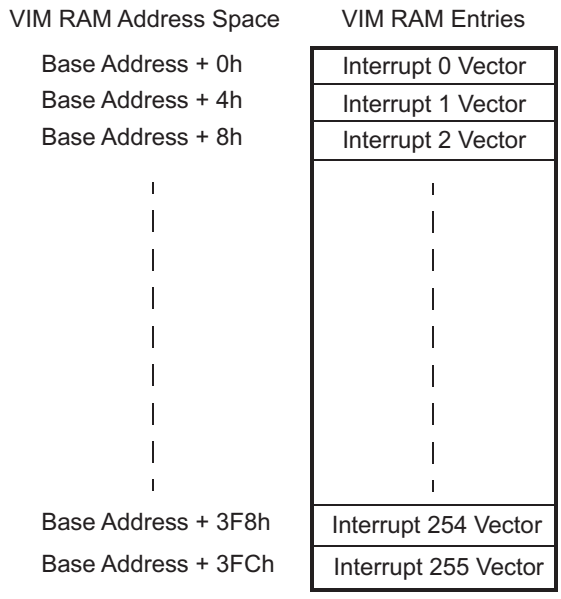

Figure 7-3. VIM RAM Interrupt Vector Map

Copyright © 2024 Texas Instruments Incorporated

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See Table 7-10 for the VIM RAM ID in the ECC aggregator map.

7.2.2.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS_VIM_FIQVEC register; IRQ: reading the R5FSS_VIM_IRQVEC register, or the *coreN_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS_VIM_FIQVEC register, or R5FSS_VIM_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ register, so that software may continue where it left off.

7.2.2.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS_VIM_DEDVEC register is used to provide the default vector for the *coreN_IRQADDRV* signal, the R5FSS_VIM_IRQVEC register, and the R5FSS_VIM_FIQVEC register. The R5FSS_VIM_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt . This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

7.2.2.5.7 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

7.2.2.5.8 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in Section 7.2.2.5.8.1, but the procedures in Section 7.2.2.5.8.2 or Section 7.2.2.5.8.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

Copyright © 2024 Texas Instruments Incorporated

For FIQs, it is recommended to use the procedure in Section 7.2.2.5.8.4, but the procedure in Section 7.2.2.5.8.5 may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.2.2.5.8.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
   a. CPU asserts *coreN_IRQACK* high
   b. VIM asserts *coreN_IRQADDRV* to indicate that the *coreN_IRQADDR* bus is stable with the correct vector address
   c. CPU reads *coreN_IRQADDR*, jumps to that address, and de-asserts *coreN_IRQACK* low
   d. VIM de-asserts *coreN_IRQn* and *coreN_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
   e. VIM loads the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, which causes the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.2.2.5.8.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS_VIM_IRQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN_IRQn* will re-assert, allowing priority interruption of an interrupt
   b. Reading this register will cause the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, and the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse

Copyright © 2024 Texas Instruments Incorporated

i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
ii. Clear the interrupt at the source

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register

4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.2.2.5.8.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS_VIM_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
   b. Optionally read the R5FSS_VIM_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_IRQSTS_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register

7.2.2.5.8.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS_VIM_FIQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN_FIQn* will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the R5FSS_VIM_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTFIQ[9:0] NUM bit field, and the R5FSS_VIM_ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source

Copyright © 2024 Texas Instruments Incorporated

ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt

4. Write any value to the R5FSS_VIM_FIQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTFIQ[31] VALID bit

7.2.2.5.8.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS_VIM_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR
   b. Optionally read the R5FSS_VIM_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_FIQSTS_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register.

7.2.2.6 WKUP_R5FSS Region Address Translation (RAT)

7.2.2.6.1 WKUP R5FSS Usage

R5 is a micro controller with 32b address, which is only able to access up to 4GB address space. However, Sitara SoC supports 36b address and majority of the memory region beyond lower 4GB are implemented. Region based address translation block, called RAT, is introduced to allow R5 core to access full 36b SoC memory map.

Each R5 core has its own RAT block, and only R5 core itself is able to program the RAT.

Figure 7-4 shows the main R5's default 32b memory map view when main R5 is out of reset.

The full RAT functionality is described in Section 7.2.2.6.2, *RAT Function*.

Copyright © 2024 Texas Instruments Incorporated

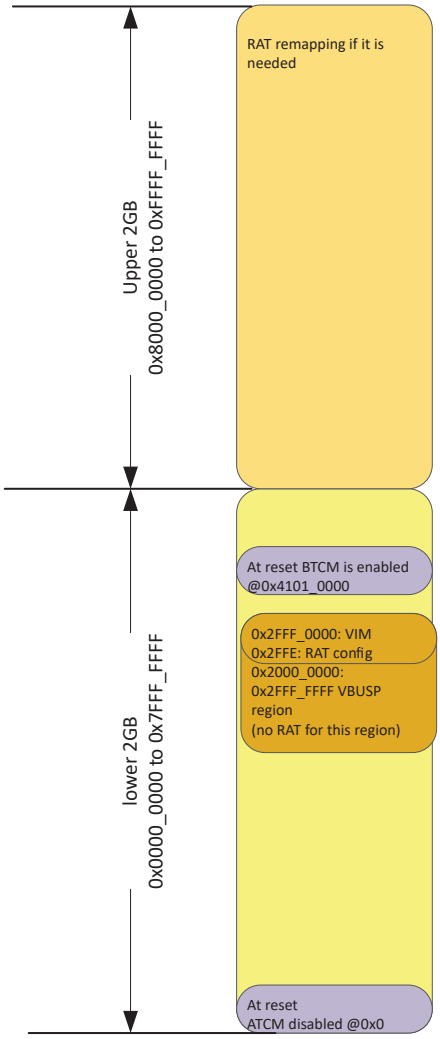

Figure 7-4. R5 Core Default Memory Map View

Copyright © 2024 Texas Instruments Incorporated

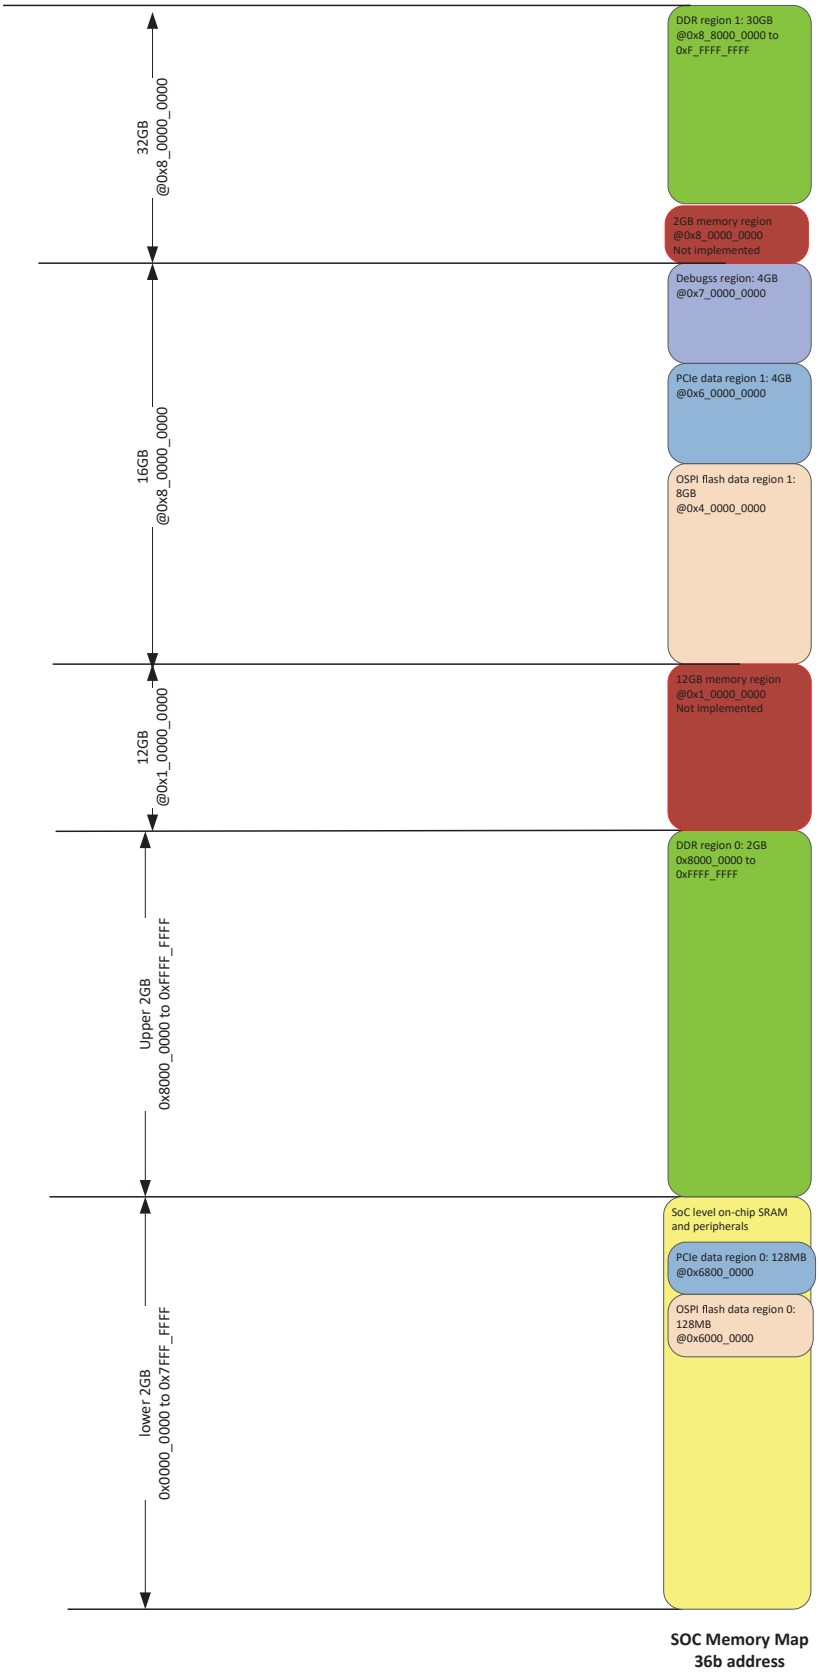

Figure 7-5. Typical Sitara SoC Memory Map View

Copyright © 2024 Texas Instruments Incorporated

RAT block enables R5 core to have full access on the SoC memory map including the memory region at and above 0x1_0000_0000.

Figure 7-6 shows how R5 access various end points, including its own ATCM, BTCM, VIM and SoC memory and peripherals. R5's ATCM is by default at address 0x0, and its BTCM is at address 0x4101_0000. R5 uses address 0x2FFF_0000 to access its VIM and 0x2FFE_0000 to access the RAT configuration region and all the other transactions between address range 0x2000_0000 to 0x2FFF_FFFF are sent to the 32b peripheral interface to access the peripherals in SoC. The transactions with the rest of address are sent to RAT block, which could go through address remapping function from original R5's 32b address to 36b SoC address.

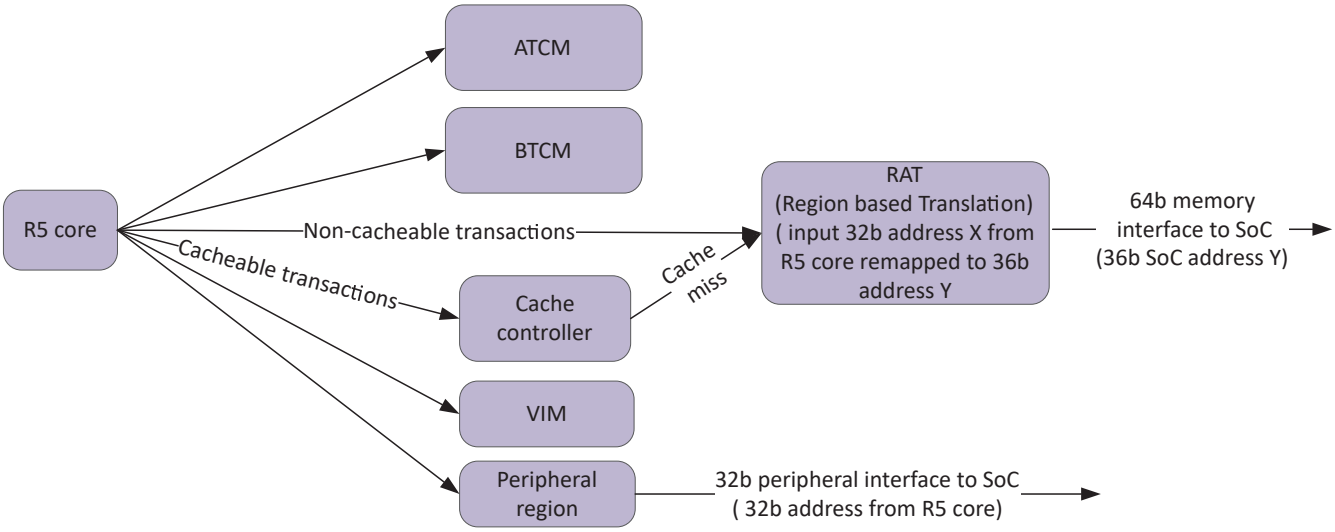

Figure 7-6. R5 Internal Address Decoding

7.2.2.6.2 RAT Function

RAT block is responsible to do a region based address translation. For each region, user can define the starting address and size of the region and remapping the transactions to use a new address range.

The starting address and region size need to be aligned. For example, if the region size is 16KB, the starting address for that region needs to be 16KB aligned. And region size should be minimum 4KB or larger to avoid transactions cross the region boundaries.

Each RAT block supports multiple programmable regions. And it is important that those regions are not overlapping with each other.

RAT block is by default disabled, which means RAT block does not do address remapping. The 32b address coming from R5 core is directly sent out to the SoC level. The user can program each RAT remapping region individually. For the transactions does not hit any remapping region, RAT block just simply forwards the transactions to the SoC level with its original address.

7.2.2.6.3 How to use RAT Block in R5

Table 7-8 shows the default R5 memory map view. Without enabling RAT function, all the regions beyond 4GB address space will not be accessible by R5.

Sitara SoC memory map is constructed the way to allow R5 and high level application processor such as A53 have similar memory map as possible. This methodology enables that R5 and ARM A53 core have a common memory map for all the SoC level memories and SoC level peripherals except a few exceptions:

- DDR's data space beyond 32b address, basically upper DDR data space beyond 2GB
- PCIe data space beyond 32b address
- OSPI data space beyond 32b address
- Debug configuration region

Copyright © 2024 Texas Instruments Incorporated

Table 7-8. R5 Memory map by Default

	R5 Memory Map(32b)	SoC Memory Map (36b)
SoC Level peripheral and on-chip SRAM	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF
2GB DDR region	Same as SoC memory map: 0x8000_0000 to 0xFFFF_FFFF	0x80000_0000 to 0xFFFF_FFFF
Additional DDR region	Not accessible	0x8_8000_0000 (30GB)
Additional 8GB OSP Space	Not accessible	0x4_0000_0000 (4GB) 0x5_0000_0000 (4GB)
Additional PCIe data space	Not accessible	0x6_000_0000
Debug configuration region	Not accessible	0x7_0000_0000

Even though all the transactions other than going to ATCM/BTCM and transactions between address range 0x2000_0000 to 0x2FFF_FFFF could use RAT block to remap to different address, it is recommended that only use RAT block to remap the R5 transactions with address between 0x8000_0000 to 0xFFFF_FFFF.

- Any transactions from R5 with address between 0x0 to 0x7FFF_FFFF are sent out to SoC directly (unless it is targeted to its internal end points such as A/B TCM, its VIM and RAT configuration)
- Only enable RAT to remap the transactions with address between 0x8000_0000 to 0xFFFF_FFFF if R5 needs to access the following address space:
  - PCIe data space at address 0x6_0000_0000
  - OSPI data space address 0x4_0000_0000 and 0x5_0000_0000
  - Debug configuration region at address 0x7_0000_0000
  - DDR data space at address 0x8_8000_0000

Copyright © 2024 Texas Instruments Incorporated

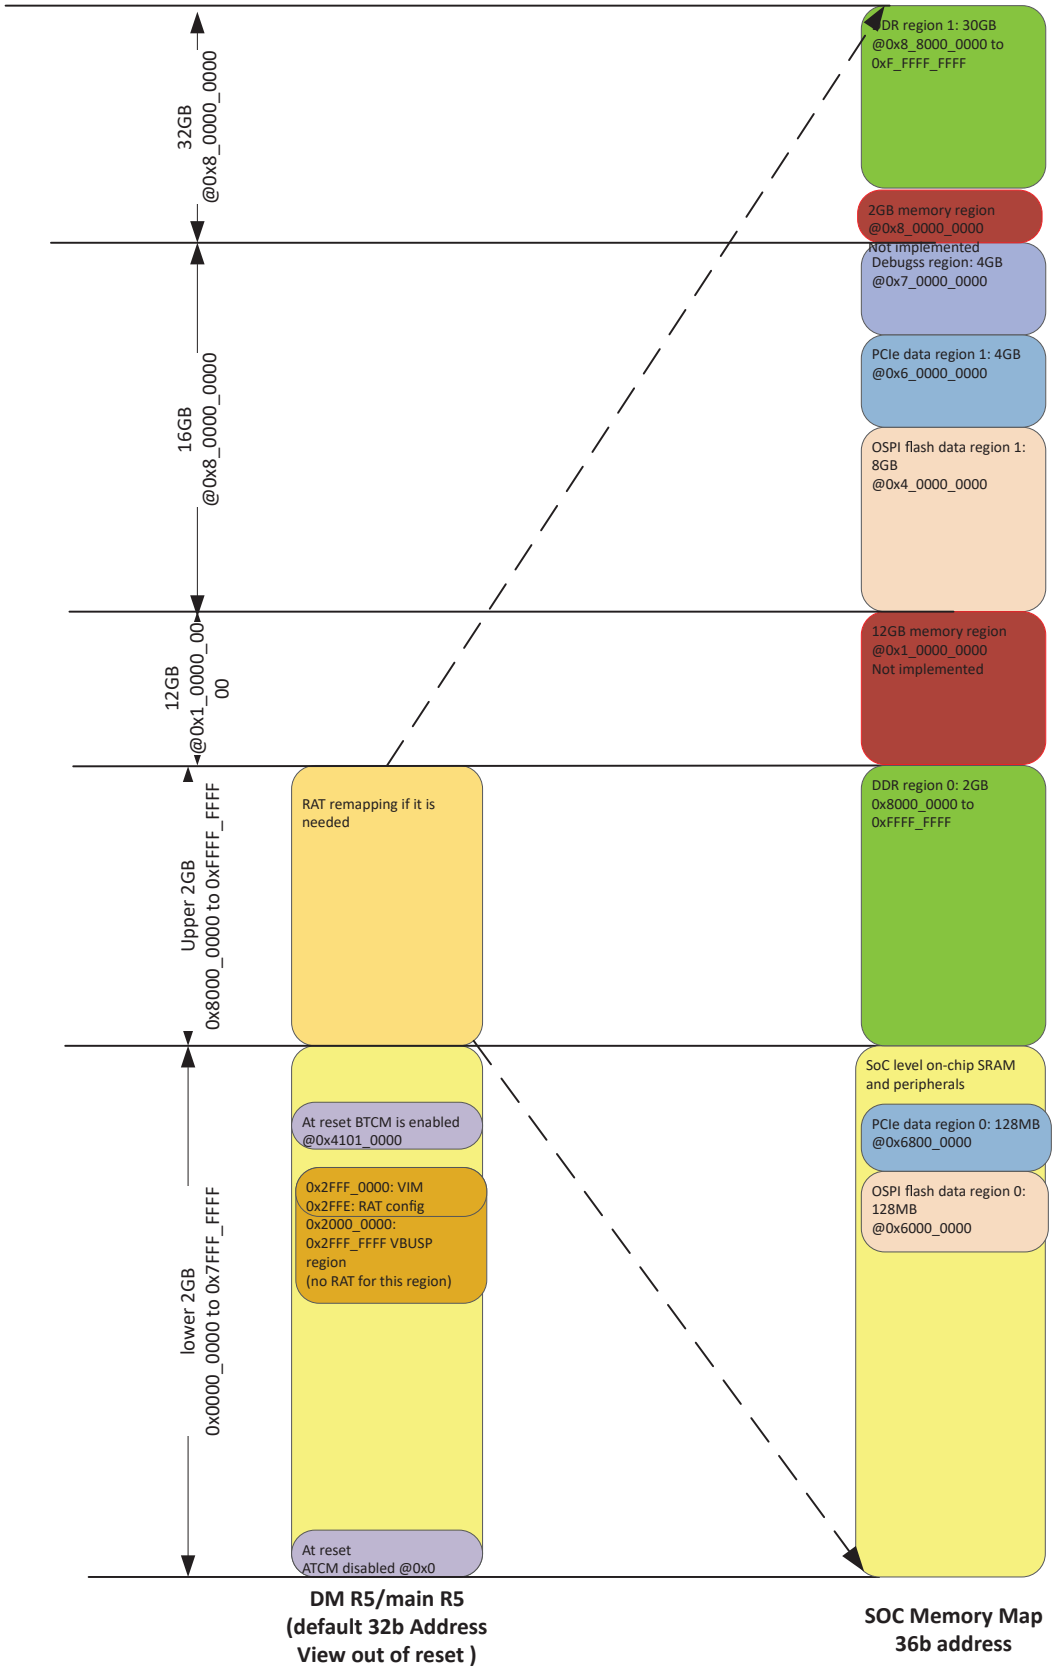

Figure 7-7. Example of Using RAT to Access Full 36b SoC Memory Map

7.2.2.6.4 Example of Using RAT to Access Full 36b SoC Memory Map

This section shows an example on how to utilize RAT block to allow R5 to access 36 SoC Memory Map. The RAT block inside R5 has up to 8 address remapping regions.

Assuming R5 needs to access the following region:

- All the SoC level on-chip SRAM
- All the SoC level peripherals
- Access 512MB OSPI region at address 0x4_0000_0000
- Access 1GB DDR region at address 0x9_0000_0000
- Access 512MB DDR region at address 0x8000_0000

First of all, we need to construct 32b R5 memory map as following and how those memory spaces are mapped to SoC level, shown in Table 7-9. Users can define where the OSPI and DDR data space placed inside R5's memory map and how they should be mapped to SoC level address map. Table 7-9 just shows one of the many possible ways to construct the memory map.

Table 7-9. Example of R5 Address Mapping

	R5 Memory Map(32b)	SoC Memory Map (36b)	RAT Remapping
SoC Level peripheral and on-chip SRAM (This is guaranteed by SoC Hardware design. No user configuration is needed)	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF	Not RAT Remapping
512MB OSPI data region (user defined)	0x8000_0000 to 0x9FFF_FFFF	0x4_0000_0000 to 0x4_1FFF_FFFF	Using RAT remapping region 0
512MB DDR space (user defined)	0xA000_0000 to 0xBFFF_FFFF	0x8000_0000 to 0x9FFF_FFFF	Using RAT remapping region 1
Additional 1GB DDR Space (user defined)	0xC000_0000 to 0xFFFF_FFFF	0x9_0000_0000 to 0x9_3FFF_FFFF	Using RAT remapping region 2

In this example, only three RAT regions are needed:

- Region 0 is used to remap R5's address between 0x8000_0000 to 0x9FFF_FFFF to SoC level address 0x4_0000_0000 to 0x4_1FFF_FFFF
- Region 1 is used to remap R5's address between 0xA000_0000 to 0xBFFF_FFFF to 0x8000_0000 to 0x9FFF_FFFF
- Region 2 is used to remap R5's address 0xc000_0000 t0 0xFFFF_FFFF to 0x9_0000_0000 to 0x9_3FFF_FFFF.

In order achieving those mappings, those are the setting of the RAT configuration registers:

	Region 0	Region 1	Region 2	Other regions
Region control register	Enabled, size set to 512MB	Enabled, size set to 512MB	Enabled, size set to 1GB	disabled
Region base(32b)	0x8000_0000	0xA000_0000	0xc000_0000	Don't care
Region translated lower address(32b)	0x0000_0000	0x8000_0000	0x0000_0000	Don't care
Region translated upper address	0x4	0x0	0x9	Don't care

Figure 7-8 shows how RAT is remapping the address between R5's 32b address to 36b SoC address.

7.2.2.7 WKUP_R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The R5F can also monitor any ECC errors on it's SoC buses and bridges through the ECC aggregator. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of the WKUP_R5FSS aggregators, see R5FSS_CPU0_ECC_AGGR_CFG_REGS Registers and R5FSS_CPU1_ECC_AGGR_CFG_REGS Registers, respectively.

Table 7-10 provides the RAM ID. This is needed for bit field [10-0] ECC_VECTOR in the corresponding R5FSS_CPU0_VECTOR**R5FSS_CPU0_VECTOR** register (part of the ECC aggregator register space).

Table 7-10. RAM ID Map for ECC Aggregator (Per Core)

7.2.2.8 WKUP_R5FSS Memory View

The memory view of the R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see Section 7.2.2.2.2.
- Peripheral interface locations: The RF5 natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map* for the complete R5F memory view for this device.

7.2.2.9 WKUP_R5FSS Interrupts

All interrupts that are generated by the WKUP_R5FSS are summarized in *Module Integration*, along with their mapping. They can be divided into the following groups:

- R5F CPU internal interrupts: These are described in *Arm Cortex-R5 Technical Reference Manual*.
- ECC aggregator interrupts: These are described in the *ECC Aggregator* chapter.
- RAT exception interrupt: This is described in Section 7.2.2.6.

7.2.2.10 WKUP_R5FSS Debug and Trace

The WKUP_R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

7.2.2.11 WKUP_R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
   a. To boot from ATCM, set CPUn_INITRAMA (or CPUn_INITRAMB to boot from BTCM)
   b. Assert CPUn_LOCZRAMA properly for the desired TCM
2. Assert CPUn_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM target port
   a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUn_HALT

Copyright © 2024 Texas Instruments Incorporated

7.2.2.12 WKUP_R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are two ECC interrupts to the ESM that aggregate different categories of ECC events – CPU single error, CPU multi error. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the WKUP_R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS_EVNT_BUS_ESM_SET register, it can be cleared by setting all the bits of the R5FSS_EVNT_BUS_ESM_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS_EVNT_BUS_ESM_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS_EVNT_BUS_ESM_CLR register to clear the interrupt.

The R5F core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5F core. For more details, refer to Arm R5 TRM.

Table 7-11. R5F Event Bus Single-Bit Error Events

7.2.3 Vectored Interrupt Manager (VIM)

This section describes the VIM module in the device.

7.2.3.1 VIM Overview

The Vectored Interrupt Manager (VIM) aggregates interrupts to a CPU. It is intended for use with a Cortex R5 from ARM. The VIM has up to 1024 interrupt inputs, which may be either level or pulse. Each interrupt has a programmable priority (0-highestthrough 15-lowest). Each interrupt may also be mapped as an IRQ or FIQ (FIQ is also often denoted as Non-Maskable Interrupt, or NMI).

7.2.3.1.1 VIM Features

- 32-1024 Interrupt inputs
  - Configurable by groups of 32
- Each interrupt has its own 4-bit programmable priority
  - Supports Priority interruption of interrupts
- Each interrupt has its own enable mask
- Each interrupt can be programmed as either an IRQ or FIQ
- Each interrupt has its own programmable 32-bit Vector address associated with it
  - Protected with SECDED
- One IRQn and FIQn output
- Vectored Interrupt Interface
  - Compatible with ARM Cortex R5 VIC Port
- Default Vector provided when a Double-Bit error is detected
- Provides clock phase inputs so VIM can run at CPU clock while interface runs at a different, synchronous clock

7.2.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

Note

Some features may not be available. See *Module Integration* for more information.

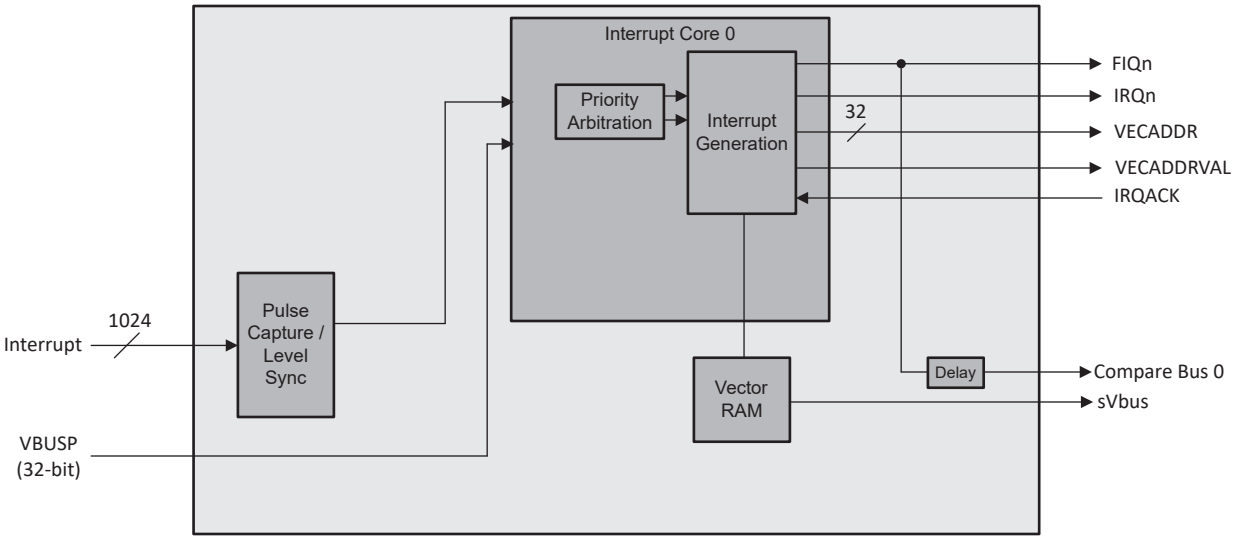
7.2.3.2 VIM Functional Description

7.2.3.2.1 Block Diagram

Figure 7-9 shows the Vectored Interrupt Manager block diagram.

Figure 7-9. VIM Block Diagram

Copyright © 2024 Texas Instruments Incorporated



7.2.3.2.2 Interrupt Inputs

The VIM can have up to 1024 interrupt inputs, build-time configurable by multiples of 32 (*num_interrupts* parameter). Each interrupt can be either a level or a pulse (both active high).

Level interrupts are synchronized to the VIM clock. This synchronized value is captured in to a flop.

Pulse interrupts use rising edge detection. Each input has its own edge detection circuit. It is recommended that if pulses are pipelined between the source and the VIM, that the pipe stage replicates the pipe flop and ORs the output in order to protect against transient errors in the pipeline flop. Once an edge has been detected, the raw status is set.

There is no minimum pulse width, as true edge detection is used. The input signal should, however, be glitch free.

7.2.3.2.3 Interrupt Outputs

The VIM has two interrupt outputs, core*N*_IRQn and core*N*_FIQn (active low levels). Each interrupt input for core *N* can be programmed to influence either the core*N*_IRQn or core*N*_FIQn output via the Group *M* Interrupt Map Register (Base Address + 0x200 + *N**0x20 + 0x18).

7.2.3.2.4 Priority Interrupt / Nested Interrupts

Each interrupt has a priority number assigned to it (set using the 4.1.20 Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q**0x4) register). Legal values are 0 to 15 where 0 is the highest priority and 15 is the lowest priority. The highest priority interrupt is the pending interrupt with the smallest priority number. If two pending interrupts have the same priority, the interrupt lowest numerically (0 through maximum number of interrupts) is prioritized. IRQs and FIQs are prioritized separately.

The VIM supports the interrupt of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate, but both use the same mechanism. When an interrupt goes from pending to active (FIQ: reading the FIQ Vector Address (Base Address + 0x1C), IRQ: reading the IRQ Vector Address (Base Address + 0x18) or the core*N*_IRQACK going high), then the interrupt is loaded into the corresponding Active Register, and all interrupts of an equal or lesser priority are masked off (see note below). If, before this interrupt is cleared (writing the FIQ Vector Address (Base Address + 0x1C) or IRQ Vector Address (Base Address + 0x18)) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. The CPU may or may not service the higher priority interrupt. If the CPU switches this interrupt to active, by reading the corresponding Vector Address Register (or core*N*_IRQACK going high for an IRQ) , then the currently active interrupt will be pushed on to a stack. When an interrupt is cleared by writing the Vector Address Register, if there are any interrupts on the stack, the first entry is popped off and put back into the Active Register, so that software may continue where it left off. Note that the IRQVEC/FIQVEC address registers are *not* repopulated with the old vector as it's assumed that the ISR is picking back up where it left off. Only the

Copyright © 2024 Texas Instruments Incorporated

interrupt number and priority are restored to the ACTIRQ/ACTFIQ registers. If software needs the vector again, it will have to read it by using the interrupt number.

Note

"Masked off" means that they are masked off from priority arbitration to interrupt the currently active interrupt, it does NOT mean that the status bits in the regsiters are masked off. i.e. this priority masking has NO EFFECT on whether the status bits are visible in the masked registers such as the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04).

7.2.3.2.5 VIC Port

The VIM is designed to work with the VIC interface of an ARM Cortex R5.

7.2.3.2.6 Latency

There are several factors that go in to the speed of processing an interrupt: the interrupt controller, the processor, and the system latency.

The VIM behaves deterministically (except for synchronizer delay). Table 7-13 shows the latency of the VIM.

Table 7-13. VIM Latency

Step	Cycles	Note
Edge Detection	2-3	Synchronizing to VIM Clock
Interrupt Capture	1	
Prioritization and Vector Read	1	IRQ Could be stalled here if an FIQ is reading the Vector RAM
		IRQ/FIQ output asserted

The next factor is the processor itself

Table 7-14. Processor Interrupt Latency

Step	Cycles(1)	Note
Take Exception		
Store State		Stack system registers etc
Read Vector	1	Through MMR or VIC interface (for IRQ. VIC interface will be faster)
Jump to Vector		

(1) These steps are dependent on the processor. See R5 spec for details.

The final factor is system latency to access the actually instructions for the ISR. This will be dependent on where the instructions are (cache, TCM, system memory etc) and dependent on the system latency to reach those memories (1 cycle for cache/TCM, System dependent for external memory)

7.2.3.2.7 Safety

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the DED Vector Address (Base Address + 0x30) is used instead for the core*N*_IRQADDRV, IRQ Vector Address (Base Address + 0x18), and FIQ Vector Address (Base Address + 0x1C). The DED Vector Address should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling. Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (say the ESM) responds to the DED interrupt that will be generated

Copyright © 2024 Texas Instruments Incorporated

It is up to the user and the application to determine the appropriate action.

An interrupt that has an uncorrectable vector error and thus uses the DED Vector, will still have the priority of the original interrupt (i.e. for masking purposes). This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by an external ECC aggregator through sVbus ports.

7.2.3.2.8 IDLE

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface because it does not have a clock IPG. To clock stop the sub-system that includes the VIM, disable (mask) all interrupts and wait for the IDLE signal to assert.

7.2.3.3 Interrupt Conditions

7.2.3.3.1 CPU Interrupts

See Table 7-15 for the interrupts generated by the module.

Table 7-15. Interrupts

Interrupt	Description
core0_IRQn	IRQ Interrupt (Active Low)
core0_FIQn	FIQ Interrupt (Active Low)

7.2.3.3.2 Interrupt Description

7.2.3.3.2.1 coreN_IRQn

This is a normal interrupt, active low level, for Core N. It can be serviced via the VIC interface or through the MMR interface.

7.2.3.3.2.2 coreN_FIQn

This is a fast (or non-maskable) interrupt, active low level, for Core N. FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface.

7.2.3.3.3 Interrupt Condition Control

7.2.3.3.3.1 coreN_IRQn

Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (Group *N* Interrupt Map Register (Base Address + 0x200 + N*0x20 + 0x18)) and is enabled (Group *N* Interrupt Enabled Set Register (Base Address + 0x200 + N*0x20 + 0x08)), and its priority is not masked (4.1.11 IRQ Priority Mask Register (Base Address + 0x28), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an IRQ to assert.

7.2.3.3.3.2 coreN_FIQn

Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ (Group *N* Interrupt Map Register (Base Address + 0x200 + N*0x20 + 0x18)) and is enabled (Group *N* Interrupt Enabled Set Register (Base Address + 0x200 + N*0x20 + 0x08)), and its priority is not masked (4.1.12 FIQ Priority Mask Register (Base Address + 0x2C)), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an FIQ to assert.

7.2.3.3.4 Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM software wants to take advantage of. For IRQs, it is recommended to use 3.4.1 IRQ through the Vector Interface, but 3.4.2 or 3.4.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives. For FIQs, it is recommended to use 3.4.4 FIQ, but 3.4.5 may be used as an alternative.

Copyright © 2024 Texas Instruments Incorporated

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.2.3.3.4.1 IRQ through the Vector Interface

If the attached CPU has the Vector Interface enabled, then the following method is used for servicing IRQs

1. Hardware handshake
   a. CPU asserts coreN_IRQACK signal high
   b. VIM asserts coreN_IRQADDRV to indicate that the coreN_IRQADDR bus is stable with the correct Vector Address
   c. CPU reads the coreN_IRQADDR, jumps to that address, and de-asserts coreN_IRQACK signal low
   d. VIM de-asserts coreN_IRQn_intr and coreN_IRQADDRV, VIM masks all IRQs with the same or lower priority
   e. VIM loads the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service an interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt
4. 4. Write any value to the IRQ Vector Address (Base Address + 0x18)
   a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
   b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

7.2.3.3.4.2 IRQ through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the Vector Interface.

1. Read the IRQ Vector Address (Base Address + 0x18) and jump to that address to service the ISR
   a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the IRQn output. If another interrupt of a higher priority becomes available, the IRQn will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group M Type Map Register (Base Address + 0x200 + M*0x20 + 0x1C) to determine type)

Copyright © 2024 Texas Instruments Incorporated

a. Pulse
   i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
   ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
b. Level
   i. Clear the interrupt at the source
   ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt

4. Write any value to the IRQ Vector Address (Base Address + 0x18)
   a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
   b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

7.2.3.3.4.3 IRQ through MMR Interface (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, priority masking will not work if route 1b is used (below) as the hardware prioritization may not match the software prioritization scheme. In this case, software would be responsible for doing all priority operations

1. Determine which interrupt to service
   a. Read the Prioritized IRQ (Base Address + 0x08) to determine which interrupt is the highest priority IRQ currently asserted OR
   b. Optionally read the IRQ Group Status (Base Address + 0x10) to determine which groups have IRQs pending, then read the Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10) and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Read the IRQ Vector Address (Base Address + 0x18)
   a. Note, this step can be done any time before step 4
   b. Value is ignored
4. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt

Copyright © 2024 Texas Instruments Incorporated

2. If the source maintains the level, then it means there is another interrupt

5. Write any value to the IRQ Vector Address (Base Address + 0x18)

7.2.3.3.4.4 FIQ

When an FIQ interrupt is received, the CPU should follow these steps.

1. Read the FIQ Vector Address (Base Address + 0x1C) and jump to that address to service the ISR
   a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the FIQn output. If another interrupt of a higher priority becomes available, the FIQn will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the Prioritized FIQ (Base Address + 0x0C) (which corresponds to the vector address) to be loaded into the Active FIQ (Base Address + 0x24) and the valid bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active FIQ (Base Address + 0x24) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt
4. Write any value to the FIQ Vector Address (Base Address + 0x1C)
   a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
   b. This will clear the valid bit of the Active FIQ (Base Address + 0x24)

7.2.3.3.4.5 FIQ (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the FIQ Vector Address (Base Address + 0x1C) is never read). Software would be responsible for doing all priority operations

1. Determine which interrupt to service
   a. Read the Prioritized FIQ (Base Address + 0x0C) to determine which interrupt is the highest priority FIQ currently asserted OR
   b. Optionally read the FIQ Group Status (Base Address + 0x14) to determine which groups have IRQs pending, then read the Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14) and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse

Copyright © 2024 Texas Instruments Incorporated

i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
ii. Clear the interrupt at the source
    1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
    1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
    2. If the source maintains the level, then it means there is another interrupt

7.2.3.4 Memory Map

Each Interrupt Core (*N* = 0) has its own MMR interface with its own independent memory map

Table 7-16. Core *N* Memory Map

Address Offset	Register
0x00	Revision Register
0x04	Info Register
0x08	Prioritized IRQ
0x0C	Prioritized FIQ
0x10	IRQ Group Status
0x14	FIQ Group Status
0x18	IRQ Vector Address
0x1C	FIQ Vector Address
0x20	Active IRQ
0x24	Active FIQ
0x28-0x2F	*Reserved*
0x30	DED Vector Address
0x34-0x1FF	*Reserved*
0x400 + *M**0x20 + 0x00	Group *M* Interrupt Raw Status/Set Register
0x400 + *M**0x20 + 0x04	Group *M* Interrupt Enabled Status/Clear Register
0x400 + *M**0x20 + 0x08	Group *M* Interrupt Enabled Set Register
0x400 + *M**0x20 + 0x0C	Group *M* Interrupt Enabled Clear Register
0x400 + *M**0x20 + 0x10	Group *M* Interrupt IRQ Enabled Status/Clear Register
0x400 + *M**0x20 + 0x14	Group *M* Interrupt FIQ Enabled Status/Clear Register
0x400 + *M**0x20 + 0x18	Group *M* Interrupt Map Register
0x400 + *M**0x20 + 0x1C	Group *M* Type Map Register
0x1000 + *Q**0x4 – 00x1FFF	Interrupt *Q* Priority Register
0x2000 + *Q**0x4 – 0x2FFF	Interrupt *Q* Vector Register

There are *M* interrupt groups (0 through *num_groups*-1) with 32 interrupts per group.

There are *Q* interrupt inputs where *Q* = *M* * 32.

Accesses to the Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4) must be word-aligned, 32-bit accesses. Any write received with no bytes enabled will be ignored. Any writes receive with all bytes enabled will be executed. Any other write will not execute and will return an error status of Addressing Error.

7.2.3.6 Programmer's Guide

7.2.3.6.1 Initialization Sequence

At initialization, the following tasks should be performed:

1. Program the DED Vector Address (Base Address + 0x30)
2. Program Group *M* Interrupt Map Register (Base Address + 0x200 + *M**0x20 + 0x18)
3. Program Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C)
4. Program Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q**0x4)
5. Program Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4)
6. Enable interrupts via the Group *M* Interrupt Enabled Set Register (Base Address + 0x400 + *M**0x20 + 0x08)

Copyright © 2024 Texas Instruments Incorporated

Note that the Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4) for each interrupt that will be enabled must be written before the interrupt is enabled, even if software is not going to use the vector. Whenever an interrupt is prioritized, the RAM location for the interrupt is read, and if that location is un-initialized, an ECC error will be reported. If the vectors aren't being used, then the RAM can be initialized by writing 0x0 to every location.

7.2.3.6.2 DED Behavior

Whenever there is 2-bit error detect on a Vector Address, the DED Vector Address (Base Address + 0x30) overrides all other vectors. Software should provide an ISR to handle this scenario at this address.

7.2.3.6.3 Power Up/Down Sequence

Before a clean power down, software should check that there are no pending interrupts, disable all interrupts, and wait for the clkstop_idle output.

7.3 Cortex-M4F Subsystem (MCU_M4FSS)

This chapter describes the Arm Cortex-M4F based safety processing microcontroller unit (MCU_M4FSS) in the device.

7.3.1 MCU_M4FSS Overview 685
7.3.2 MCU_M4FSS Functional Description 686

Copyright © 2024 Texas Instruments Incorporated

7.3.1 MCU_M4FSS Overview

The MCU_M4FSS is an Arm Cortex-M4F based subsystem that can run safety processing or be used as a general purpose MCU. During the boot process, the MCU_M4FSS will be configured by an initial software running on a different core. Following configuration, software will release the safety processor (M4F) out of reset, and at this point safety processor code or general purpose code can start execution.

Note

The Cortex-M4F processor is a Cortex-M4 processor that includes the optional floating point unit (FPU) extension.

The MCU_M4FSS is designed to meet SIL-2 safety requirements. Safety is enabled for all major subsystem components that include ECC / EDC features:

- ECC: I-RAM, D-RAM
- EDC: I-RAM, D-RAM, ECC_AGGR, RAT, CBASS, AHB2VBUSP bridges

There is one MCU_M4FSS in the device. Table 7-26 shows MCU_M4FSS allocation across device domains.

Table 7-26. MCU_M4FSS Allocation Across Device Domains

Module Instance	Domain	
	MCU	MAIN
MCU_M4FSS0	✓	–

7.3.1.1 MCU_M4FSS Features

The MCU_M4FSS supports the following features:

- Arm Cortex-M4F RISC CPU
  - Single-core implementation
  - Core revision is r0p1
  - Armv7-M architecture
  - Memory protection unit (MPU)
  - Nested vectored interrupt controller (NVIC), to achieve low interrupt latency
    - 64 external interrupts
    - 3-bit priority (8 priority levels)
  - Bus interfaces
    - Three advanced high-performance bus-lite (AHB-Lite) interfaces: ICode, DCode, and system bus interfaces
    - Private peripheral bus (PPB) based on advanced peripheral bus (APB) interface
- 256KB SRAM memory system divided into two banks
  - 192KB of instruction code (I-RAM)
  - 64KB of data space (D-RAM)
- Ability to execute code from internal SRAMs or external memories
- External initiators can access internal SRAMs if allowed
- 32-bit to 36-bit region-based address translation (RAT)
- Fault detection and correction
  - SECDED ECC protection on I-RAM
  - SECDED ECC protection on D-RAM
  - Fault error interrupt generation
- Standard Arm debug and trace architecture

Note

Some features may not be available. See *Module Integration* for more information.

7.3.2 MCU_M4FSS Functional Description

7.3.2.1 MCU_M4FSS Block Diagram

Figure 7-10 shows the MCU_M4FSS block diagram.

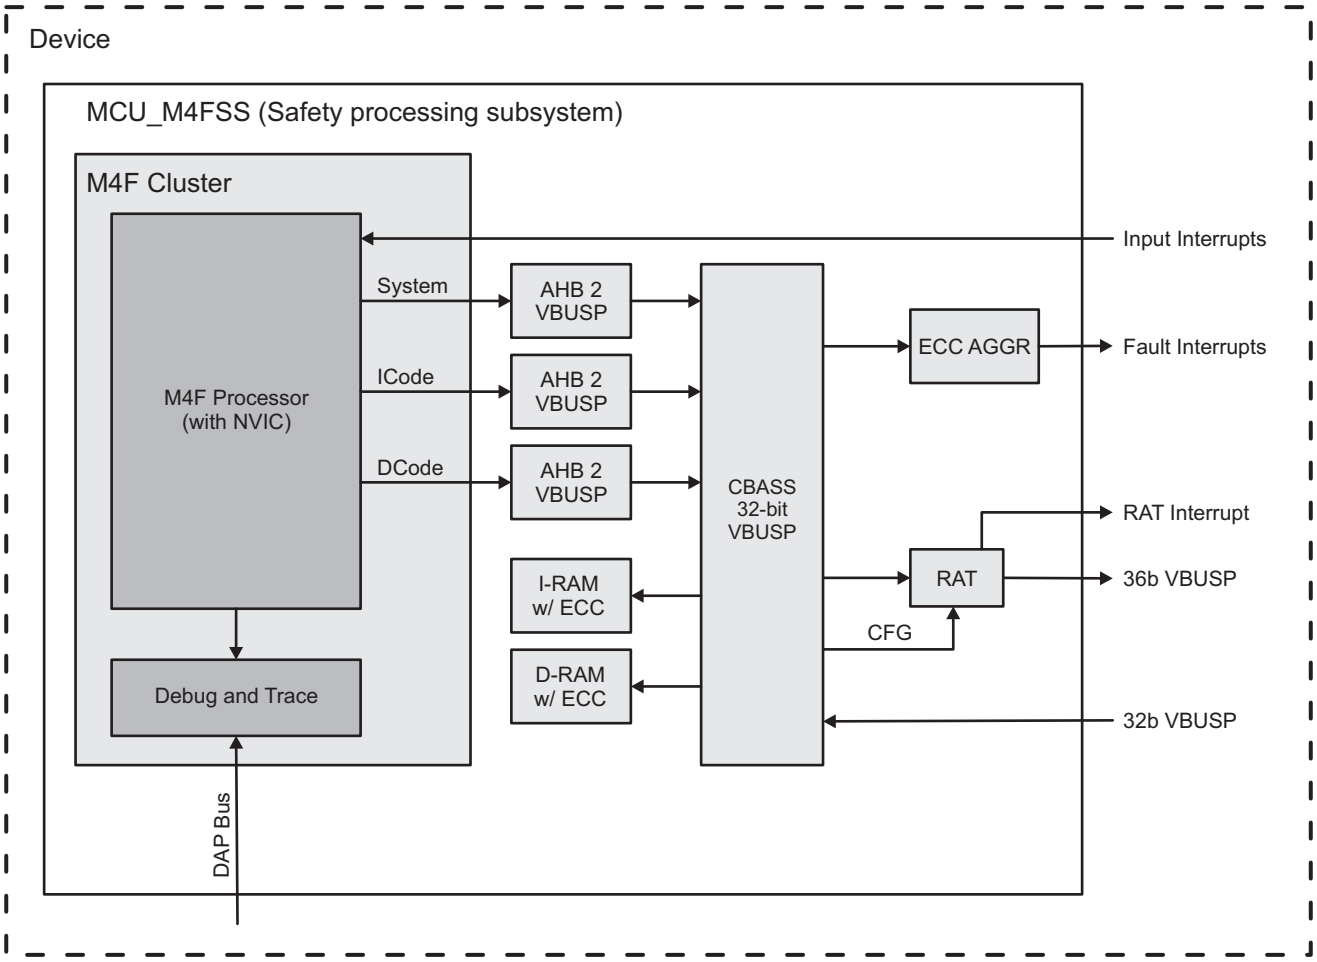

Figure 7-10. MCU_M4FSS Block Diagram

7.3.2.2 MCU_M4FSS Processor

The M4F is a low-power processor that features low gate count, low interrupt latency, and low-cost debug. It is intended for deeply embedded applications that require optimal interrupt response features. Some key features of the M4F processor core include:

- A subset of the Thumb instruction set, defined in the Armv7-M architecture
- Banked stack pointer (SP)
- Hardware integer divide instructions, SDIV and UDIV
- Handler and thread modes
- Thumb and debug states
- Support for interruptible-continued instructions LDM, STM, PUSH, and POP for low interrupt latency

A nested vectored interrupt controller (NVIC) is closely integrated with the processor core, to achieve low latency interrupt processing. NVIC features include:

- 64 external interrupts
- 3-bit priority (8 priority levels)
- Dynamic reprioritization of interrupts
- Priority grouping

Copyright © 2024 Texas Instruments Incorporated

  - This enables selection of preempting interrupt levels and non-preempting interrupt levels
- Support for tail-chaining and late arrival of interrupts
  - This enables back-to-back interrupt processing without the overhead of state saving and restoration between interrupts
- Processor state automatically saved on interrupt entry, and restored on interrupt exit, with no instruction overhead

The M4F processor also includes:

- Bus interfaces for memory access (ICode, DCode, system) and debug access (PPB APB)
- Memory protection unit (MPU)
- Various debug and trace units

For more details on the M4F processor, refer to the following documents:

- *Arm Cortex-M4 Processor Technical Reference Manual*
- *Arm Cortex-M4 Devices Generic User Guide*

7.3.2.3 MCU_M4FSS Internal RAMs

The MCU_M4FSS has a total of 256KB of SRAM divided into two banks: 192KB of I-RAM, and 64KB of D-RAM. The I-RAM memory is intended mainly for M4F's instruction code, and D-RAM for M4F's data. The M4F allows concurrent fetch for instruction code and data via dedicated buses (I-Code and D-Code, respectively).

The MCU_M4FSS supports unified memory for both banks (I-RAM and D-RAM), which means instruction code and data can be placed in any bank. In order to get optimal performance, it is highly recommend that instruction code be placed in I-RAM and data be placed in D-RAM; this allows the M4F to fetch in parallel instruction code and data from two different physical banks using two independent I-Code and D-Code buses. For instance, the D-RAM can be used to store instruction code in case the latter is spanning over the 192KB I-RAM.

Furthermore, the following applies:

- Both RAMs are organized in 32-bits words
- Both RAMs are initialized during reset - that is, there is no auto-initialization sequencing
- Both RAMs are ECC SECDED protected
  - Support for write-back upon single bit correction
- Data fetch is given higher priority over instruction fetch to avoid locking M4F

7.3.2.4 MCU_M4FSS Interfaces

7.3.2.4.1 Controller Interfaces

The MCU_4FSS has three 32-bit advanced high-performance bus-lite (AHB-Lite) interfaces:

- ICode for instructions
- DCode for data
- System bus

7.3.2.4.2 Peripheral Interfaces

The MCU4FSS has two peripheral interfaces:

- 32-bit VBUSP configuration interface - ECC Aggregator block
- 32-bit Debug interface

7.3.2.5 MCU_M4FSS Power, Clocking and Reset

See specific integration, power, clocking, and reset chapters.

7.3.2.6 MCU_M4FSS Memory View

The M4F processor has a fixed default memory map that provides up to 4GB of addressable memory. The predefined memory map allows the built-in peripherals, such as NVIC, MPU, SysTick and debug components, to be accessed by simple memory access instructions. Thus, most system features are accessible in program code. The M4F design has an internal bus infrastructure optimized for this memory usage.

Copyright © 2024 Texas Instruments Incorporated

The MCU_M4FSS memory map is presented in *Memory Map*. Note that bit-banding is not supported.

7.3.2.7 MCU_M4FSS RAT

7.3.2.7.1 RAT Usage

M4F is a micro controller with 32b address, which is only able to access up to 4GB address space. However, Sitara SoC supports 36b address and majority of the memory region beyond lower 4GB are implemented. Region based address translation block, called RAT, is introduced to allow R5 core to access full 36b SoC memory map.

Each R5 core has its own RAT block, and only R5 core itself is able to program the RAT.

Figure 7-11 shows the main R5's default 32b memory map view when main R5 is out of reset.

The full RAT functionality is described in *Region-based Address Translation (RAT) Module*.

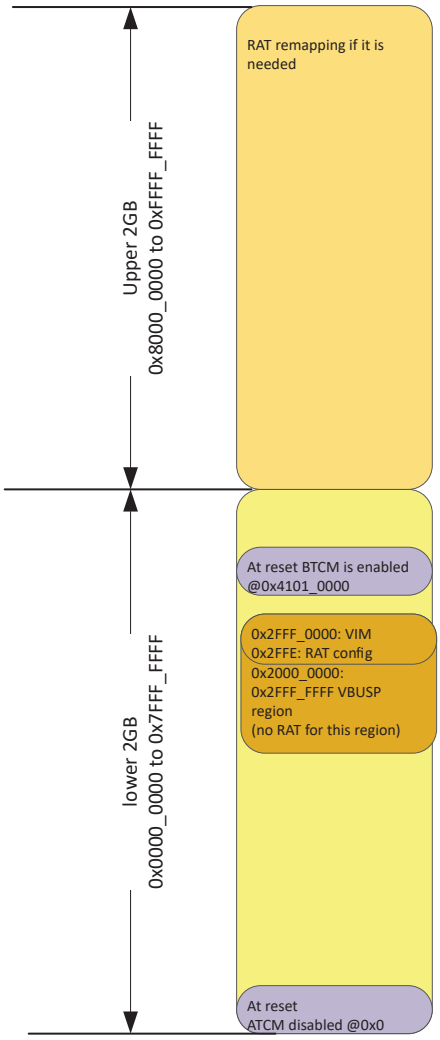

Figure 7-11. R5 Core Default Memory Map View

Copyright © 2024 Texas Instruments Incorporated

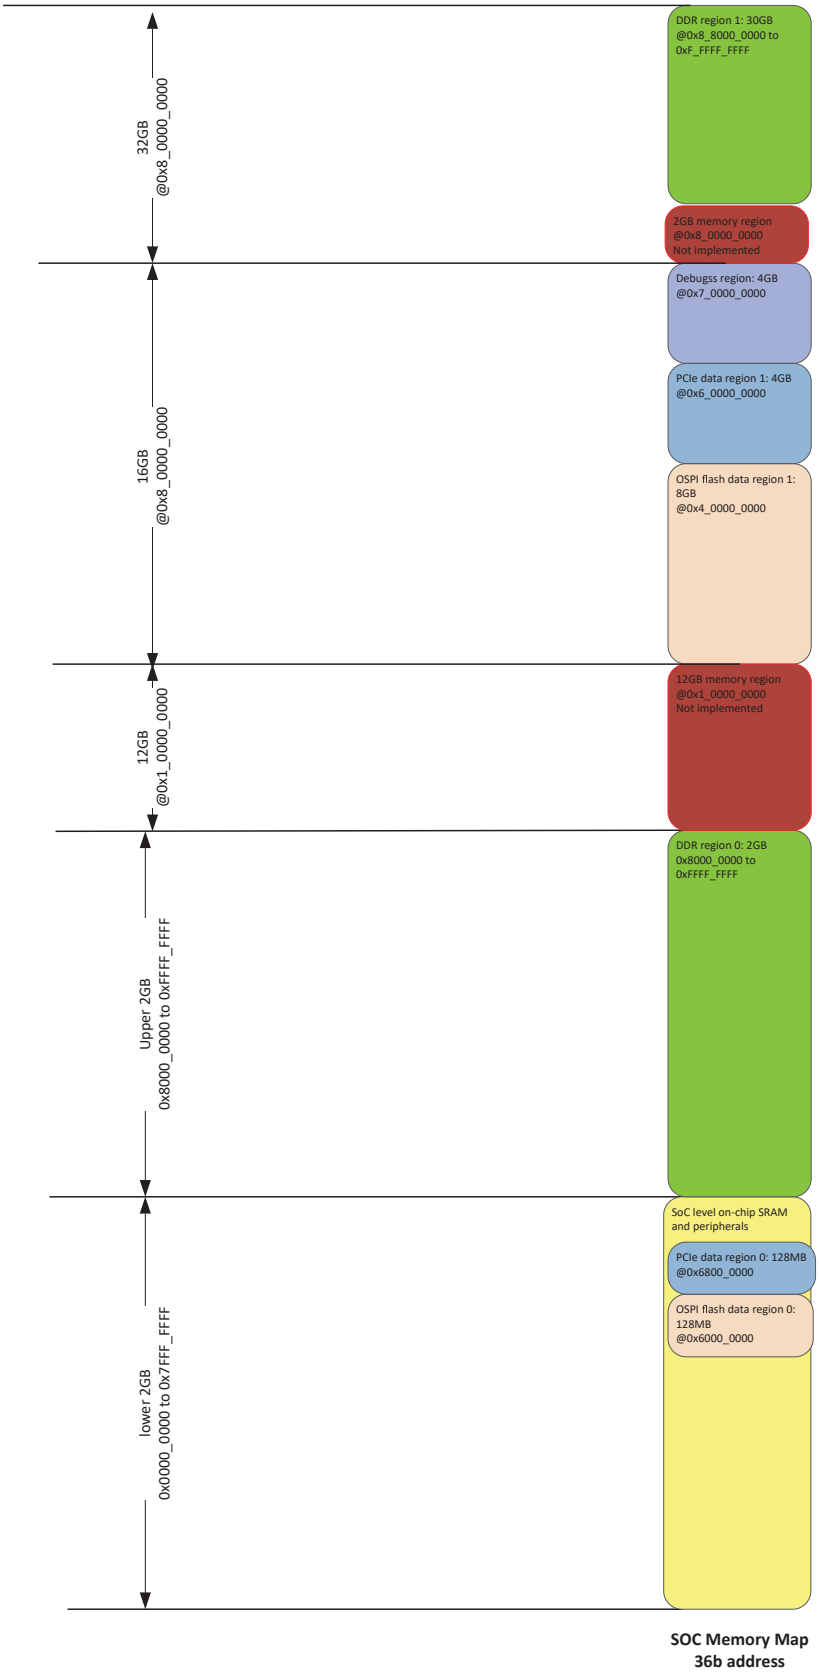

Figure 7-12. Typical Sitara SoC Memory Map View (36b address)

Copyright © 2024 Texas Instruments Incorporated

RAT block enables R5 core to have full access on the SoC memory map including the memory region at and above 0x1_0000_0000.

Figure 7-13 shows how R5 access various end points, including its own ATCM, BTCM, VIM and SoC memory and peripherals. R5's ATCM is by default at address 0x0, and its BTCM is at address 0x4101_0000. R5 uses address 0x2FFF_0000 to access its VIM and 0x2FFE_0000 to access the RAT configuration region and all the other transactions between address range 0x2000_0000 to 0x2FFF_FFFF are sent to the 32b peripheral interface to access the peripherals in SoC. The transactions with the rest of address are sent to RAT block, which could go through address remapping function from original R5's 32b address to 36b SoC address.

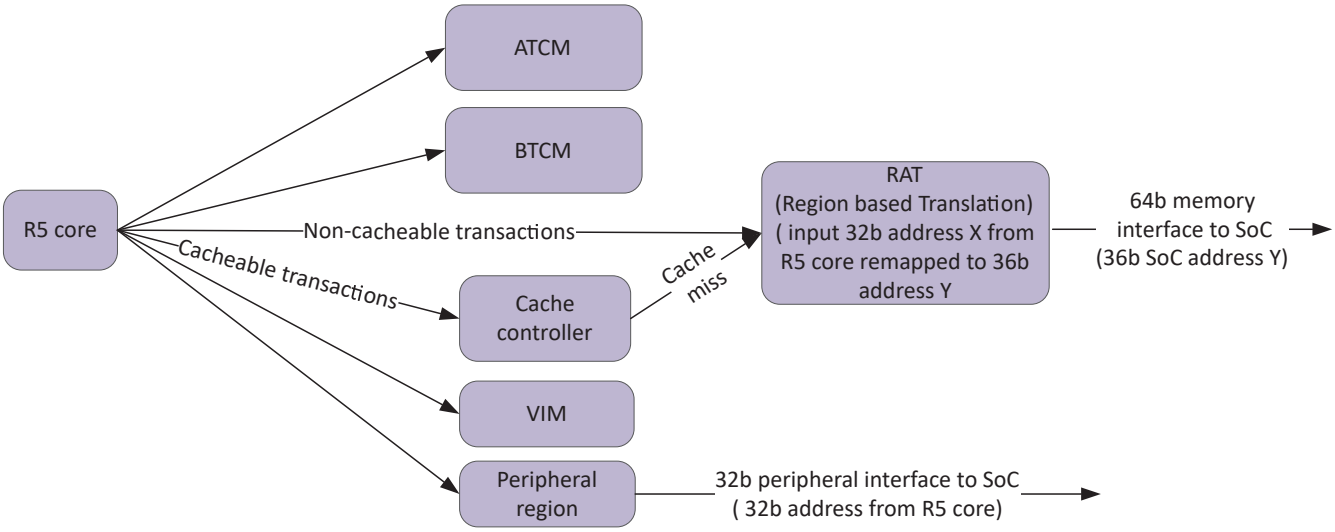

Figure 7-13. R5 Internal Address Decoding

Table 7-27. MCU R5 Memory Map View

Starting Address	End Address	Region	Notes
0x 0000_ 0000	0x0000_ 7FFF	ATCM	ATCM is by default disabled. Before it is enabled, its address can be remapped to a different location through CP15. Access from othre masters uses the SoC level memory address assigned to ATCM.
0x0000_ 8000	0x03FF_FFFF	sent to SoC leve through 64b VBUSM initiator	
0x0400_0000	0x07FD_FFFF	peripheral region. Sent to SoC level to access the SoC level peripherals in address range of 0x2000_0000 to 0x2FFD_FFFF.	
0x07FE_0000	0x07FE_0FFF	R5's own RTA configuration region	
0x07FF_0000	0x07FF_3FFF	R5's own VIM	
0x0800_0000	0x410F_FFFF	sent to SoC leve through 64b VBUSM initiator. Do not use RAT for address remapping.	
0x4101_0000	0x4101_7FFF	R5's BTCM	BTCM by default is enabled. And access from SoC level uses the SoC level memory address assigned to BTCM.
0x4101_8000	0x7FFF_FFFF	sent to SoC leve through 64b VBUSM initiator. Do not use RAT for address remapping.	

Copyright © 2024 Texas Instruments Incorporated

Table 7-27. MCU R5 Memory Map View (continued)

Starting Address	End Address	Region	Notes
0x8000_0000	0xFFFF_FFFF	Could use RAT for address remapping if it is needed before sent to 64b VBUSM initiator.	

7.3.2.7.2 RAT Function

RAT block is responsible to do a region based address translation. For each region, user can define the starting address and size of the region and remapping the transactions to use a new address range.

The starting address and region size need to be aligned. For example, if the region size is 16KB, the starting address for that region needs to be 16KB aligned. And region size should be minimum 4KB or larger to avoid transactions cross the region boundaries.

Each RAT block supports multiple programmable regions. And it is important that those regions are not overlapping with each other.

RAT block is by default disabled, which means RAT block does not do address remapping. The 32b address coming from R5 core is directly sent out to the SoC level. The user can program each RAT remapping region individually. For the transactions does not hit any remapping region, RAT block just simply forwards the transactions to the SoC level with its original address.

7.3.2.7.3 How to use RAT Block in R5

Table 7-28 shows the default R5 memory map view. Without enabling RAT function, all the regions beyond 4GB address space will not be accessible by R5.

Sitara SoC memory map is constructed the way to allow R5 and high level application processor such as A53 have similar memory map as possible. This methodology enables that R5 and ARM A53 core have a common memory map for all the SoC level memories and SoC level peripherals except a few exceptions:

- DDR's data space beyond 32b address, basically upper DDR data space beyond 2GB
- PCIe data space beyond 32b address
- OSPI data space beyond 32b address
- Debug configuration region

Table 7-28. R5 Memory map by Default

	R5 Memory Map(32b)	SoC Memory Map (36b)
SoC Level peripheral and on-chip SRAM	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF
2GB DDR region	Same as SoC memory map: 0x8000_0000 to 0xFFFF_FFFF	0x80000_0000 to 0xFFFF_FFFF
Additional DDR region	Not accessible	0x8_8000_0000 (30GB)
Additional 8GB OSP Space	Not accessible	0x4_0000_0000 (4GB) 0x5_0000_0000 (4GB)
Additional PCIe data space	Not accessible	0x6_000_0000
Debug configuration region	Not accessible	0x7_0000_0000

Even though all the transactions other than going to ATCM/BTCM and transactions between address range 0x2000_0000 to 0x2FFF_FFFF could use RAT block to remap to different address, it is recommended that only use RAT block to remap the R5 transactions with address between 0x8000_0000 to 0xFFFF_FFFF.

- Any transactions from R5 with address between 0x0 to 0x7FFF_FFFF are sent out to SoC directly (unless it is targeted to its internal end points such as A/B TCM, its VIM and RAT configuration)
- Only enable RAT to remap the transactions with address between 0x8000_0000 to 0xFFFF_FFFF if R5 needs to access the following address space:
  - PCIe data space at address 0x6_0000_0000

Copyright © 2024 Texas Instruments Incorporated

- OSPI data space address 0x4_0000_0000 and 0x5_0000_0000
- Debug configuration region at address 0x7_0000_0000
- DDR data space at address 0x8_8000_0000

Copyright © 2024 Texas Instruments Incorporated

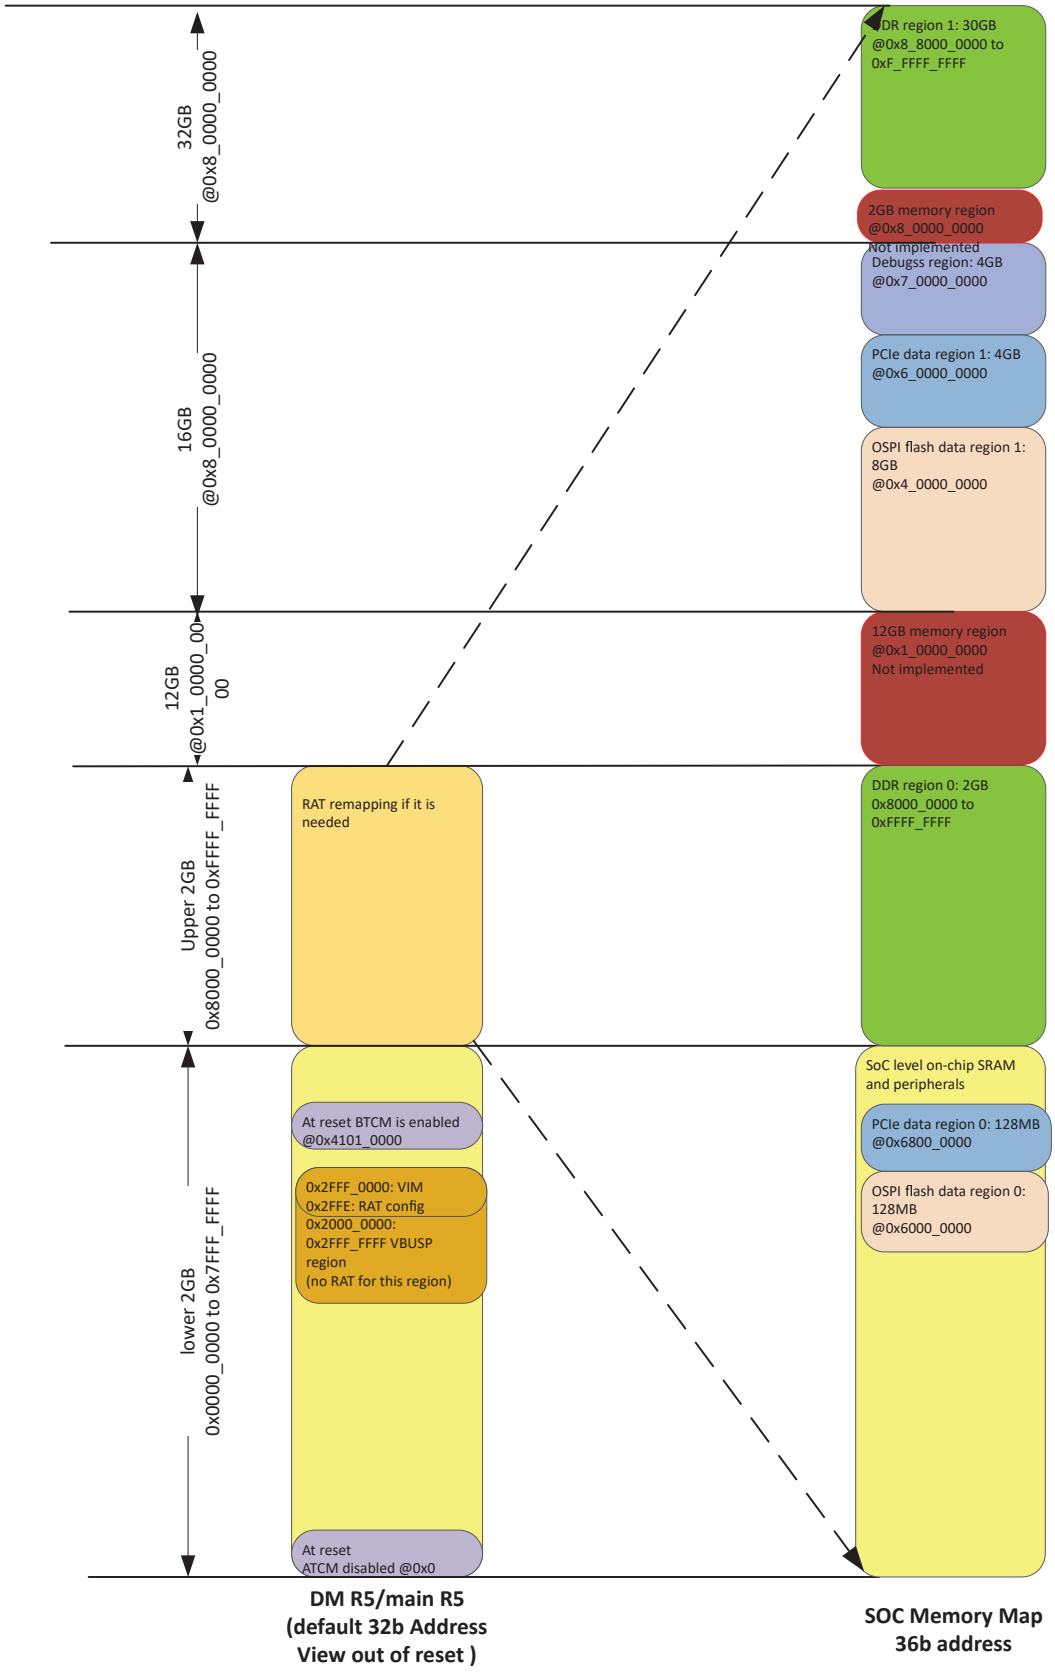

Figure 7-14. Main R5 RAT Configuration

7.3.2.7.4 Example of Using RAT to Access Full 36b SoC Memory Map

This section shows an example on how to utilize RAT block to allow R5 to access 36 SoC Memory Map. The RAT block inside R5 has up to 8 address remapping regions.

Assuming R5 needs to access the following region:

- All the SoC level on-chip SRAM
- All the SoC level peripherals
- Access 512MB OSPI region at address 0x4_0000_0000
- Access 1GB DDR region at address 0x9_0000_0000
- Access 512MB DDR region at address 0x8000_0000

First of all, we need to construct 32b R5 memory map as following and how those memory spaces are mapped to SoC level, shown in Table 7-29. Users can define where the OSPI and DDR data space placed inside R5's memory map and how they should be mapped to SoC level address map. Table 7-29 just shows one of the many possible ways to construct the memory map.

Table 7-29. Example of R5 Address Mapping

	R5 Memory Map(32b)	SoC Memory Map (36b)	RAT Remapping
SoC Level peripheral and on-chip SRAM (This is guaranteed by SoC Hardware design. No user configuration is needed)	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF	Not RAT Remapping
512MB OSPI data region (user defined)	0x8000_0000 to 0x9FFF_FFFF	0x4_0000_0000 to 0x4_1FFF_FFFF	Using RAT remapping region 0
512MB DDR space (user defined)	0xA000_0000 to 0xBFFF_FFFF	0x8000_0000 to 0x9FFF_FFFF	Using RAT remapping region 1
Additional 1GB DDR Space (user defined)	0xC000_0000 to 0xFFFF_FFFF	0x9_0000_0000 to 0x9_3FFF_FFFF	Using RAT remapping region 2

In this example, only three RAT regions are needed:

- Region 0 is used to remap R5's address between 0x8000_0000 to 0x9FFF_FFFF to SoC level address 0x4_0000_0000 to 0x4_1FFF_FFFF
- Region 1 is used to remap R5's address between 0xA000_0000 to 0xBFFF_FFFF to 0x8000_0000 to 0x9FFF_FFFF
- Region 2 is used to remap R5's address 0xc000_0000 t0 0xFFFF_FFFF to 0x9_0000_0000 to 0x9_3FFF_FFFF.

In order achieving those mappings, those are the setting of the RAT configuration registers:

	Region 0	Region 1	Region 2	Other regions
Region control register	Enabled, size set to 512MB	Enabled, size set to 512MB	Enabled, size set to 1GB	disabled
Region base(32b)	0x8000_0000	0xA000_0000	0xc000_0000	Don't care
Region translated lower address(32b)	0x0000_0000	0x8000_0000	0x0000_0000	Don't care
Region translated upper address	0x4	0x0	0x9	Don't care

Figure 7-15 shows how RAT is remapping the address between R5's 32b address to 36b SoC address.

7.3.2.8 MCU_M4FSS ECC Support

The MCU_M4FSS includes an ECC aggregator module that combines ECC errors from various local sources, such as RAMs, interconnects and bridges. Table 7-30 provides the mapping of ECC errors within the MCU_M4FSS ECC aggregator. Two separate interrupts are generated for ECC error: correctable and non-correctable.

The full ECC aggregator functionality is described in *ECC Aggregator*.

Table 7-30. "Fault Detected" Interrupt Mapping for MCU_M4FSS ECC Aggregator

Interrupt Number (RAM ID)	Source
0	Iram_ramecc_pend

7.3.2.9 MCU_M4FSS Interrupts

See specific integration chapter.

7.3.2.10 MCU_M4FSS Debug and Trace

The MCU_M4FSS supports the following debug and trace features:

- Full debug, including data matching for watchpoint generation
- Full trace, including ITM, ETM and DWT
  - HTM port is not present
  - TPIU is not present
- DAP interface
- ITM and ETM interfaces
- CTM crossbar to map CTI triggers to CTM channels through a CS_CTI module
- Debug infrastructure is reset with POR reset

7.3.2.11 MCU_M4FSS Time Sync

The MCU_M4FSS supports a 48-bit input interface for synchronizing to the global time counter (GTC). The 48-bit timestamp can be appended with ITM messages. Timestamping is a mechanism whereby a global timestamp value is periodically inserted at strategic locations into the trace stream. Timestamps can be used to correlate trace from various sources. Each trace source samples the timestamp value and inserts it as an absolute value into the trace stream.

The global timestamp value coming to the MCU_M4FSS is gray-encoded. It is then internally converted to its binary value.

For more details on the device time synchronization, refer to the following sections:

- *Global Timebase Counter (GTC)*

Copyright © 2024 Texas Instruments Incorporated

- *Time Sync*

7.3.2.12 MCU_M4FSS SysTick

The MCU_M4FSS includes a 24-bit count-down system timer (SysTick) that can be used as a real time operating system (RTOS) tick timer or as a simple counter. The MCU_M4FSS_SYSTICK register in the MCU_CTRL_MMR module provides the calibration settings required for proper SysTick operation.

7.3.2.13 MCU_M4FSS Initialization

The MCU_M4FSS has a local reset input. This input is driven by PSC, but controlled by software (PSC MMRs, with programmable default state). This local reset resets just the M4F processor. When the PSC (controlled by software) brings the MCU_M4FSS out of reset, the M4F CPU is held in reset through this local reset, but everything else will be running (except debug logic). This allows to pre-load the RAMs in the MCU_M4FSS. Software then releases the local reset and M4F starts executing the pre-loaded code in the RAMs.

Software can repeat the initialization process over and over by following these steps:

1. Execute WFI instruction
2. Transition MCU_M4FSS to a DISABLE/OFF state through PSC (PSC will wait for MCU_M4FSS to be IDLE which includes MCU_M4FSS asserting WFI)
3. Transition MCU_M4FSS to an ENABLE/ON state through PSC (local reset will be held asserted)
4. Pre-load RAMs
5. Release local reset

7.4 Programmable Real-Time Unit Subsystem (PRUSS)

This section describes the Programmable Real-Time Unit Subsystem in the device.

Note

The supported set of features and peripherals is device part number dependent. For more information, see the device datasheet.

Note

The PRU Subsystem (PRUSS) is a subset of the PRU Industrial Communication Subsystem (PRU-ICSS) found on other TI processors. The superset names "PRU-ICSS", and "ICSSM" are used in some parts of the TRM to refer to the PRU Subsystem. Reference the PRU-ICSS Module Integration section for information about PRU-ICSS features that are unsupported in PRU-ICSS.

7.4.1 PRUSS Overview

The Programmable Real-Time Unit Subsystem (PRUSS) consists of:

- Two 32-bit load/store RISC CPU cores — Programmable Real-Time Units (PRU0 and PRU1)
- Data RAMs per PRU core (DRAM)
- Instruction RAMs per PRU core (IRAM)
- Shared RAM (SRAM)
- Peripheral modules: UART0, ECAP0, IEP0, MDIO
- Interrupt Controller (INTC) per core

The programmable nature of the PRU cores, along with their access to pins, events and all device resources, provides flexibility in implementing fast real-time responses, specialized data handling operations, custom peripheral interfaces, and in offloading tasks from the other processor cores of the device.

The PRU cores are programmed with a small, deterministic instruction set. Each PRU can operate independently or in coordination with each other and can also work in coordination with the device-level host CPU. This interaction between processors is determined by the nature of the firmware loaded into the PRU's instruction memory.

7.4.1.1 PRUSS Key Features

The PRUSS subsystem includes the following main features:

- Two 32-bit load/store RISC CPU cores — Programmable Real-Time Units (PRU0 and PRU1), each with:
  - 20 Enhanced General-Purpose Inputs (EGPI) and 20 Enhanced General-Purpose Outputs (EGPO)
  - Asynchronous capture [Serial Capture Unit (SCU)] with 3-channel peripheral interface and Sigma-Delta demodulation support
    - The 3-channel peripheral interface supports multiple different encoder protocols such as EnDAT 2.2, HDSL, and Tamagawa.
  - program memory per PRU (PRU0_IRAM and PRU1_IRAM) with ECC
  - MAC (Multiplier with optional Accumulation)
  - CRC16/CRC32 hardware accelerator
  - RX XFR2VBUS
- Scratchpad Memory (SPAD) with 3 banks of 30 × 32-bit registers:
  - 3 banks for the PRU0 and PRU1 cores
- 32 KB Shared general purpose memory RAM with ECC (Data RAM2), shared between PRU0 and PRU1
- Two 8 KB (shared) Data Memories with ECC (Data RAM0 and Data RAM1)
- 36-bit VBUSM Controller Port:
  - Optional address translation for all transactions to External Host
- 16 Software Events generated by 2 PRUs
- One Enhanced Capture Module (ECAP0)

Copyright © 2024 Texas Instruments Incorporated

- Interrupt Controller (INTC)
  - Up to 32 internal events, generated by modules, internal to the PRUSS
  - Up to 32 external events, generated by the system
  - Supports up to 10 interrupt channels
  - Generation of 8 Host interrupts:
    - 8 Host interrupts, exported from the PRUSS for signaling the Arm interrupt controllers (pulse and level provided)
  - Each system event can be enabled and disabled
  - Each host event can be enabled and disabled
  - Hardware prioritization of events
- One 32-bit VBUSP target port for memory mapped register and internal memories access
- Flexible power management support
- Integrated 32-bit Interconnect

Note

Some features may not be available. See *Module Integration* for more information.

Copyright © 2024 Texas Instruments Incorporated

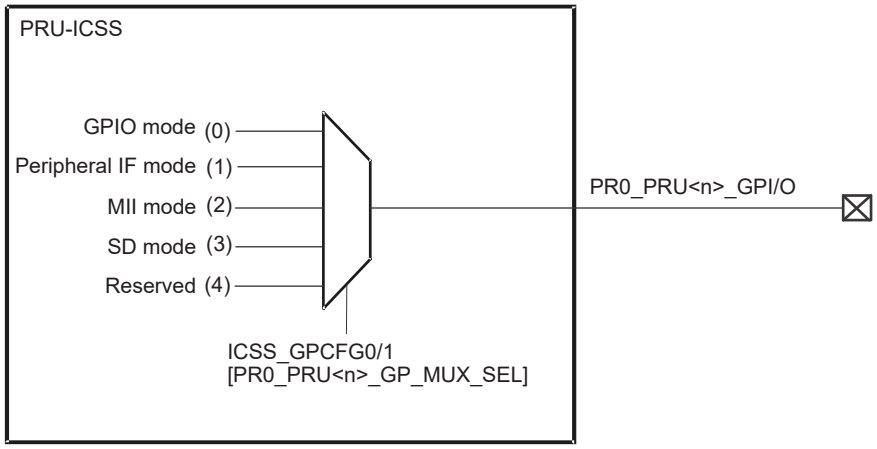
7.4.2 PRUSS Environment

This section describes the PRUSS external connections (environment).

7.4.2.1 PRUSS Internal Pinmux

The PRUSS external interface signals are described in Table 7-31. The PRUSS has a large number of available I/O signals. Most of these are multiplexed with other functional signals at the device level.

The PRUSS also support an internal wrapper multiplexing that expands the device top-level multiplexing. This wrapper multiplexing is controlled by the GPCFGx_REG register (where x = 0 or 1) in the PRUSS CFG register space and allows MII_RT, 3 channel Peripheral Interface (with EnDAT capabilities), and Sigma Delta functionality to be muxed with the PRU GPI/O device signals, as shown in Figure 7-16. The PRUSS wrapper multiplexing is described with the device-level signals in Table 7-31. Note that the device top-level muxing has higher priority over the internal PRUSS muxing.



1. n represents a valid instance of PRU in a domain.

Figure 7-16. PRUSS Internal Wrapper Multiplexing

Note

Additionally to PRUSS wrapper multiplexing the device I/O logic maps the PRUSS signals to the different device pins by programming the associated IOMUX CTRLMMR register.

(1) I = Input; O = Output
(2) HiZ = High Impedance
(3) The PRU internal pinmux mapping provided in the TRM is part of the original hardware definition of the PRU. However, due to the flexibility provided by the IP and associated firmware configuraitons, this is not necessarily a hard requirement. The first PRU implementation for AM65x had the MII TX pins swapped during initial SoC integration and this convention was maintained for subsequent PRU revisions to enable firmware reuse. To make use of the SDK firmware, use the SYSCONFIG generated PRU pin mapping.

7.4.2.2 PRUSS Fast GPIO pins

Each PRUSS PRU processor implements fast general purpose outputs (GPO) through its R30 register and fast general purpose inputs (GPI) through its R31 register. The device multiplexes all GPI signals and their corresponding GPO signals onto the same device pin using different device multiplexing modes. In some applications it may be necessary for the PRU to switch between GPO and GPI operation in a fast (or at least a deterministic) manner. This is not possible using SoC level pin muxing since each pin being switched requires a write to a separate pin configuration register located in Control Module (CTRL_MMR0).

In order to address the fast switching issue, special I/O pin connectivity for the PRUSS GPO/GPI pins is implemented. This feature makes use of the IEP EDIO signal controls to provide input/output switching using a single SoC level pin multiplexing mode.

The IEP EDIO interface has 32 data input (DATA_IN) and 32 data output (DATA_OUT) signals. It also has a set of 32 corresponding data output enable (DATA_OUT_EN) signals to be used as (active low) output driver enables to allow each DATA_OUT/DATA_IN to be implemented as a bidirectional pin. On this device, only 4 of the IEP EDIO I/Os of each PRUSS module are pinned out (PRG[2:0]_IEP_EDIO_DATA_IN_OUT[31:28]). This leaves a majority of the DATA_OUT_EN signals unused. The device allows these unused output enables to be optionally re-purposed for use as GPO enables. This allows each PRUSS GP pin to function as either a GPO or as a GPI when the I/O pin is configured for the GPO muxmode.

A set of SoC level registers (CTRLMMR_ICSS[2:0]_CTRL[2:0]) are used to determine the behavior of each GPO mode pin. When a register's [19-0]GPM_BIDI bit field is set to 0h (default value), the corresponding GPO pin operates only as an output when the GPO multiplexing mode is selected and is driven with the R30 bit value. The corresponding GPI signal (PRUSS GPI<n> input, where n = 0 to 19) is driven low. When a register's [19-0]GPM_BIDI bit field is set to 1h, the corresponding ICSS_DIGIO_DATA_OUT_EN_REG[31-0] DATA_OUT_EN bit field is used to control the GPO output buffer. If [31-0] DATA_OUT_EN bit field is set to 0h the output is driven and the pin acts as a GPO. If [31-0] DATA_OUT_EN bit field is set to 1h the output is disabled and the pin acts as a GPI.

The PRU[1:0]_GPM[19:0] output signals are propagated to the PRG_PRU[1:0]_GPO[19:0] pins using Muxmode 0 function and the PRU[1:0]_GPN[19:0] input signals are propagated to the PRG_PRU[1:0]_GPI[19:0] pins using Muxmode 1 function. Any GPO (Muxmode 0 function) can be made bidirectional by setting the corresponding bit field [19-0]GPM_BIDI in CTRLMMR_ICSS_CTRL[2:0] register.

7.4.3 PRUSS Top Level Resources Functional Description

This section provides functional description of the device integrated PRU Subsystems modules.

The PRUn (where n = 0 or 1) cores within each PRUSS have access to all resources on the SoC through the VBUSM Interface Controller port, and the external host processors can access the PRUSS resources through the VBUSP Interface Target port. The use of XFR2VBUS allows BroadSide 32Bytes of data transfer to/from SoC CBASS0 Interconnect at 256-bit bursts using the VBUSM Controller port. The 32-bit Internal CBASS Interconnect bus will be the primary interconnect between all components internal to the PRUSS. There are two equally symmetrical halves in each PRUSS known as SLICE0 and SLICE1. Each slice will share several resources while capable of working independently of each other. There are two sets of XFR2VBUS for each Slice. PRUs also has the ability to submit 32-bit bursts transitions, but this will require RAT configuration.

Each of the Slices contains one RAT (Region based Address Translation) module. The RAT module is used to translate 32-bit address of the PRU core to 48-bit physical address.

The PRU cores within the subsystems also have access to all resources on the SoC through the External CBASS0 Interconnect. A subsystem local Interrupt Controller — INTC handles system input events and posts events back to the device-level host CPUs.

Figure 7-18 shows an overview of the PRUSS Functional Block Diagram.

Figure 7-18. PRUSS Functional Block Diagram

Table 7-32 summarizes the mapping between hardware modules and PRU0/1 cores.

Table 7-32. Hardware Module Broadside ID Mapping

Hardware Module	Broadside ID	
MPY/MAC	00	2 copies: PRU1/0
CRC16/32	01	2 copies: PRU1/0
SPAD Bank0	10	shared between PRU1/0
SPAD Bank1	11	shared between PRU1/0
SPAD Bank2	12	shared between PRU1/0
RX L2	20/21	2 copies: PRU1/0
TX L2	40	2 copies: PRU1/0
XFR2VBUSP	0x60 for RD_ID0 0x61 for RD_ID1 0x62 for WD_ID0 0x63 for WD_ID1	2 copies shared of RX per SLICE 2 copies shared of TX per SLICE

7.4.3.1 PRUSS Reset Management

The device supports warm reset isolation (Hard/Soft Reset, Watchdog Reset) on PRUSS.

7.4.3.2 PRUSS Power and Clock Management

The PRUSS supports two levels of clock gating. First level gates all clocks inside the PRUSS when requested by the . The second level allows user software to enable/disable clocks in the clock gating register ICSS_CGR_REG to some internal modules, as follows:

- IEP
- ECAP0
- UART0
- INTC

The appropriate configuration registers block controls its local module set inside PRUSS.

Copyright © 2024 Texas Instruments Incorporated

7.4.3.2.1 PRUSS CORE Clock Generation

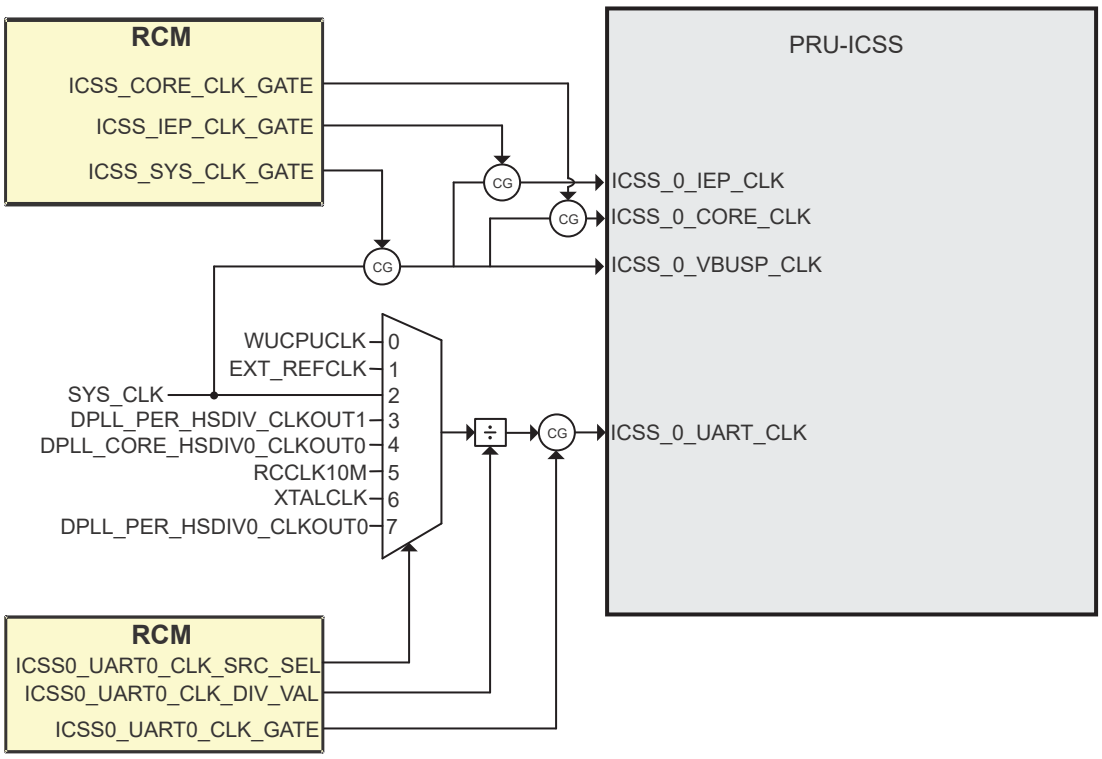

Figure 7-19. PRU-ICSS Clock Diagram

The CORE, BUS, and IEP Clock all use the 200 MHz SYS_CLK as a source clock. The UART clock is configurable by configuring the UART clock source select register as well as the UART clock divider value register. Each of these clock sources has a configurable clock gate that can be configured with the appropriate clock gate register

7.4.3.2.2 PRUSS Idle State

The below lists the clock management settings applicable at PRUSS subsystem level (first level of local power management).

A transition from an ACTIVE/Normal state to an IDLE state is performed as per the sequence:

1. The host processor requests that the PRU firmware goes into IDLE state and waits for acknowledgement.
2. The host issues Clock Stop Request for each module in the PRU_ICSS_CGR register with gateable clocks defined at second power management level (see Section 7.4.3.2)
3. The PRUSS acknowledges IDLE Request and send Clock Stop Acknowledge to the host processor.
4. The PSC can de-assert PWR_CLK_EN
5. The main clocks can get turned off

A transition from an IDLE state to an ACTIVE/ Normal state is performed as per the sequence:

1. Turn on the main external clocks
2. The PSC can assert PWR_CLK_EN
3. The host will need to de-assert Clock Stop Request for each module, defined in PRU_ICSS_CGR register,
4. The PRUSS firmware need to de-assert Clock Stop Acknowledge for each module defined in PRU_ICSS_CGR register and then wait for the Clock Stop Acknowledge de-assert

Copyright © 2024 Texas Instruments Incorporated

5. The PRUSS firmware will de-assert Clock Stop Acknowledge

7.4.3.2.3 PRUSS Protect

Write protect block allows software to enable safety protection to prevent corruption of key configuration and debug registers and the Instruction memories (IRAM's) of all PRU cores (PRU0/PRU1). Write protection is also supported for Data RAM0 and Data RAM1.

This is achived by blocking the byte enables during a write transaction if enabled. When enabled, it will prevent any unwanted write transaction to these elements. To Enable/Disable this feature, software will first need to unlock the write access to this block through the PROT_UNLOCK_KEY register then configure the protection through PROT_CFG register and relock.

7.4.3.2.4 Module Clock Configurations at PRUSS Top Level

IEP functional clock source selection: The clock source selection to the IEP module is done in register CTRLMMR_PRU_ICSS_CLKSEL[19-16] IEP_CLKSEL (where n = 0 or 1) in the CTRL_MMR0 location. For more information on these PRUSS level input clocks, refer to the *PRUSS Integration*.

Enhanced GPIO clock divider settings: In certain sample/shift clock settings of the PRU0 and PRU1 EGPIOs (when enabled in serial mode) two cascaded fractional dividers are done in the PRU_ICSS_CFG top level configuration registers PRU_ICSS_GPCFG0 and PRU_ICSS_GPCFG1. In addition, EGPIO clock active edge selection control can be exerted via the bit PRU0_GPI_CLK_MODE for PRU0 EGPIO and PRU1_GPI_CLK_MODE for the PRU1 EGPIO.

- For the serial PRU0's EGPOs:
  - PRU_ICSSM_GPCFG0_REG[24-20] PRU0_GPO_DIV1
  - PRU_ICSSM_GPCFG0_REG[19-15] PRU0_GPO_DIV0
- For the serial PRU0's EGPIs:
  - PRU_ICSSM_GPCFG0_REG[12-8] PRU0_GPI_DIV1
  - PRU_ICSSM_GPCFG0_REG[7-3] PRU0_GPI_DIV0
- For the serial PRU1's EGPOs:
  - PRU_ICSSM_GPCFG1_REG[24-20] PRU1_GPO_DIV1
  - PRU_ICSSM_GPCFG1_REG[19-15] PRU1_GPO_DIV0
- For the serial PRU1's EGPIs:
  - PRU_ICSSM_GPCFG1_REG[12-8] PRU1_GPI_DIV1
  - PRU_ICSSM_GPCFG1_REG[7-3] PRU1_GPI_DIV0

7.4.3.3 Other PRUSS Module Functional Registers at Subsystem Level

Enhanced GPIO. The other functional mode setting for PRUs EGPIOs at PRUSS top registers level are:

- PRU_ICSSM_GPCFG0 / PRU_ICSSM_GPCFG1[14] PRU0_GPO_MODE (PRU0 or PRU1) — to select between direct or serial EGPO output mode of operation.
- PRU_ICSSM_GPCFG0 / PRU_ICSSM_GPCFG1[25] PRU0_GPO_SH_SEL (PRU0 or PRU1) — to select between the EGPO shadow registers 0 and 1 used for output shifting. For more details, refer to the Section 7.4.4.2.2.3.4, *Enhanced General-Purpose Module Outputs (R30)*.
- PRU_ICSSM_GPCFG0 / PRU_ICSSM_GPCFG1[1-0] PRU0_GPI_MODE (PRU0 or PRU1) — selects the EGPI input mode of operation (selects between "direct input", "parallel capture", "28-bit shift" or "MII_RT" modes).
- PRU_ICSSM_GPCFG0 / PRU_ICSSM_GPCFG1[13] PRU0_GPI_SB (PRU0 or PRU1) — start bit event status for 28-bit EGPI input shift mode. For more details, refer to the Section 7.4.4.2.2.3, *Enhanced General-Purpose Module Inputs (R31)*.

7.4.3.4 PRUSS Memory Maps

The PRUSS comprises various distinct addressable regions that are mapped to both a local and global memory map. The local memory maps are maps with respect to the PRU point of view. The global memory maps are maps with respect to the Host point of view, but can also be accessed by the PRUSS. Each PRUSS can also

Copyright © 2024 Texas Instruments Incorporated

access the memories within the other PRUSS subsystem without going through an external port, thanks to PRUSS VBUSP expansion port.

7.4.3.4.1 PRUSS Local Memory Map

The PRUSS memory map is documented in Table 7-33 (Instruction Space) and in Table 7-34 (Data Space). Note that these two memory maps are implemented inside the PRUSS and are local to the components of the PRUSS.

7.4.3.4.1.1 PRUSS Local Instruction Memory Map

Each PRU (PRU0 and PRU1) has a dedicated 16KB of Instruction Memory (16KB for PRUSS) which needs to be initialized by an external to PRUSS Host processor before a PRU core executes any instructions.

CAUTION

The PRUSS PRU0/1_IRAM regions are ONLY accessible from controllers, external to the PRUSS (like Arm) when the PRU0/PRU1 is NOT running. The access is via PRUSS target port on the device CBASS0 interconnect.

Table 7-33. PRUSS Local Instruction Memory Map

Start Address	PRU0	PRU1
0000 0000h	16 KB IRAM	16 KB IRAM

7.4.3.4.1.2 PRUSS Local Data Memory Map

The local data memory map in Table 7-34 allows each PRU core to access the PRUSS addressable regions (both its own subsystem and the other subsystem) and the external host's memory map.

Table 7-34. PRUSS Local Data Memory Map

Start Address	PRU0	PRU1
0000 0000h	Data 8KB RAM0	Data 8KB RAM1
0000 2000h	Data 8KB RAM1	Data 8KB RAM0

0003 3000h	MII_G_RT_CFG	MII_G_RT_CFG

7.4.3.4.2 PRUSS Global Memory Map

The global view of the PRUSS internal memories and control ports is shown in Table 7-35. The offset addresses of each region are implemented inside the PRUSS but the global device memory mapping places the PRUSS target port in the address range shown in the external PRUSS Host top-level memory map.

Copyright © 2024 Texas Instruments Incorporated

The global memory map is with respect to the Host point of view (that is, device Arm), but it can also be accessed by the PRUSS itself. Note that PRU0 and PRU1 can use either the local or global addresses to access their internal memories, but using the local addresses provides access time several cycles faster than using the global addresses. This is because when accessing via the global address the access has to be routed through the CBASS0 switch fabric outside PRUSS and back in through the PRUSS target port.

Each of the PRU cores can access the rest of the device memory (including memory mapped peripheral and configuration registers) using the global memory space addresses.

Table 7-35. PRUSS Global Memory Map

Offset Address	PRUSS Target
0000 0000h	Data 8 KB RAM0
0000 2000h	Data 8 KB RAM1

7.4.4 PRUSS PRU Cores

This section describes the functionality of the two Programmable Real-time Unit (PRU) processors (PRU0 and PRU1), integrated in the device PRUSS.

7.4.4.1 PRU Cores Overview

The PRU is a processor optimized for performing embedded tasks that require manipulation of packed memory mapped data structures, handling of system events that have tight real-time constraints and interfacing with systems external to the SoC. The PRU is both very small and very efficient at handling such tasks.

The major attributes of the PRU are shown in Table 7-36.

Table 7-36. PRU Features

Attribute	Value
IO Architecture	Load/Store
Data Flow Architecture	Register to Register
Core Level Bus Architecture	
Type	4-Bus Harvard (1 Instruction, 3 Data)
Instruction I/F	32-Bit Modified VBUSP Controller
Memory I/F 0	32-Bit VBUSP Controller
Memory I/F 1	32-Bit VBUSP Controller
Execution Model	
Issue Type	Scalar
Pipelining	None (Purposefully)
Ordering	In Order
ALU Type	Unsigned Integer
Registers	
General Purpose (GP)	30 (R1 – R30)
External Status	0 (R31)
GP/Indexing	0 (R0)
Addressability in Instruction	Bit, Byte (8-bit), Half-word (16-bit), Word (32-bit), Pointer
Addressing Modes	
Load Immediate	16-bit Immediate
Load/Store – Memory	Register Base + Register Offset Register Base + 8-bit Immediate Offset Register Base with auto increment/decrement Constant Table Base + Register Offset Constant Table Base + 8-bit Immediate Offset Constant Table Base with auto increment/ decrement
Data Path Width	32-bit
Instruction Width	32-bit
Accessibility to Internal PRU Structures	Provides 32-bit VBUSP target with three regions: • Instruction RAM • Control/Status registers • Debug access to internal registers (R0-R31) and constant table

The processor is based on a four-bus architecture which allows instructions to be fetched and executed concurrently with data transfers. In addition, an input is provided in order to allow external status information

Copyright © 2024 Texas Instruments Incorporated

to be reflected in the internal processor status register. Figure 7-20 shows a block diagram of the processing element and the associated instruction RAM/ROM that contains the code that is to be executed.

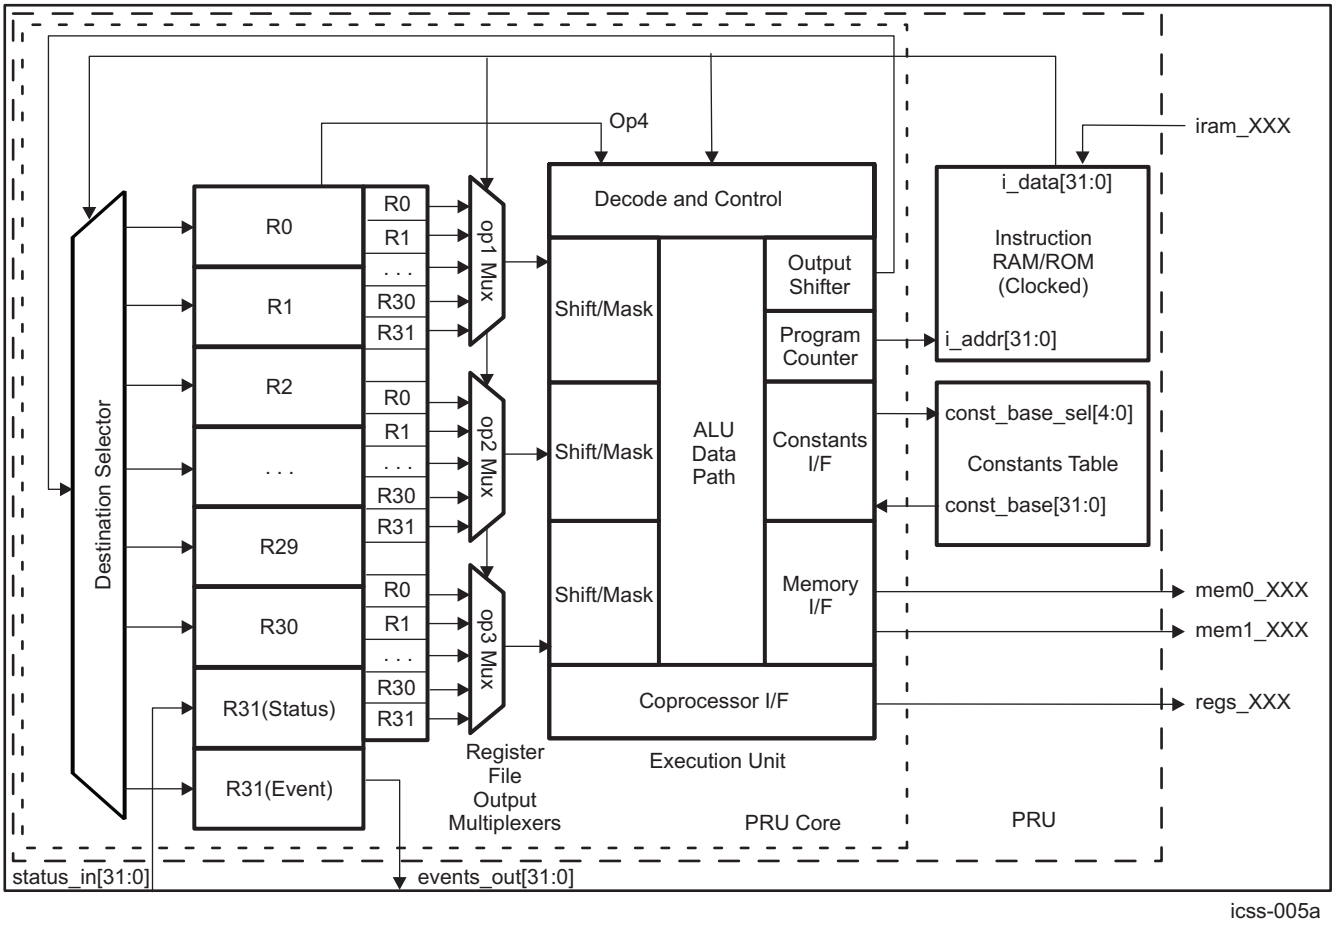

Figure 7-20. PRU Block Diagram

7.4.4.2 PRU Cores Functional Description

This section describes the PRU cores supported functionality by describing the constant table, module interface and enhanced GPIOs.

7.4.4.2.1 PRU Constant Table

The PRU Constants Table is a structure of hard-coded memory addresses for commonly used peripherals and memories. The constants table is used for more efficiently load/store data to these commonly accessed addresses by:

- Eliminating the PRU instruction that pre-loads a hard-coded address into the internal register file.
- Maximizing the usage of the PRU register file for embedded processing applications by moving many of the commonly used constant or deterministically calculated base addresses from the internal register file to an external table.

Table 7-37. PRU0/1 Constant Table

Entry No.	Region Pointed To	Value [31:0]
0	PRUSS INTC (local)	0002_0000h
1	PRUSS IEP (local)	0002_F000h
2	PRUSS IEP_0x100 (local)	0002_F100h
3	PRUSS ECAP0 (local)	0003_0000h

23	Reserved	C000_0000h
24	PRUSS PRU0/PRU1 Data RAM (local)	0000_0n00h, n = c24_blk_index[3:0]
25	PRUSS PRU1/PRU0 Data RAM (local)	0000_2n00h, n = c25_blk_index[3:0]
26	PRUSS IEP (local)	0002_En00h, n = c26_blk_index[3:0]
27	PRUSS MII_RT/SGMII0_CFG/SGMII1_CFG (local)	0003_2n00h, n = c27_blk_index[3:0]
28	PRUSS Shared RAM (local)	00nn_nn00h, nnnn = c28_pointer[15:0]
29	RESERVED	0Dnn_nn00h, nnnn = c29_pointer[15:0]
30	RESERVED	0Enn_nn00h, nnnn = c30_pointer[15:0]
31	RESERVED	0Fnn_nn00h, nnnn = c31_pointer[15:0]

Note

The addresses in constants entries 24–31 are partially programmable. Their programmable bit field (for example, c24_blk_index[3:0]) is programmable through the PRU CTRL register space. As a general rule, the PRU should configure this field before using the partially programmable constant entries.

7.4.4.2.2 PRU Module Interface

The PRU module interface consists of the PRU internal registers 30 and 31 (R30 and R31). Figure 7-21 shows the PRU module interface and the functionality of R30 and R31. The register R31 serves as an interface with the dedicated PRU general purpose input (GPI) pins and PRUSS INTC. Reading R31 returns status information from the GPI pins and PRUSS INTC via the PRU Real Time Status Interface. Writing to R31 generates PRU

Copyright © 2024 Texas Instruments Incorporated

system events via the PRU Event Interface. The register R30 serves as an interface with the dedicated PRU general purpose output (GPO) pins.

Note

The below sections cover different functional modes of the PRUn cores, (where n=0,1), enhanced GPIO (EGPIO) interface. The register bits which control EGPIO functionalities are part of the (PRUSS CFG) space. For descriptions of these EGPIO register bitfield controls, refer to the Section 7.4.3.3.

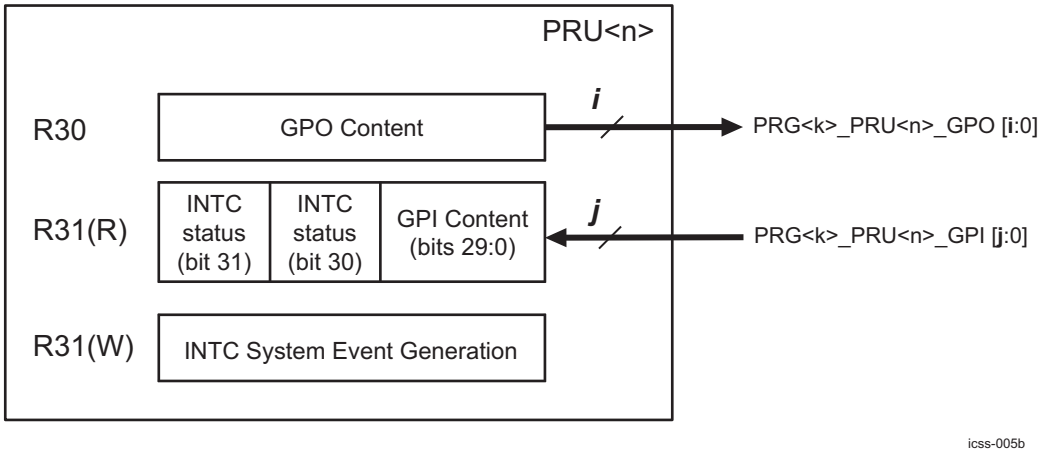

Figure 7-21. PRU Module Interface

7.4.4.2.2.1 Real-Time Status Interface Mapping (R31): Interrupt Events Input

The PRU Real Time Status Interface directly feeds information into register 31 (R31) of the PRU's internal register file. The firmware on the PRU uses the status information to make decisions during execution. The status interface is comprised of signals from different modules inside of the PRUSS which require some level of interaction with the PRU. More details on the Host interrupts imported into bit 30 and 31 of register R31 of both the PRUs is provided in the , *PRUSS Local Interrupt Controller*.

Table 7-38. Real-Time Status Interface Mapping (R31) Field Descriptions

Bit	Field	Description
31	pru_intr_in[1]	PRU Host Interrupt 1 from local PRUSS INTC
30	pru_intr_in[0]	PRU Host Interrupt 0 from local PRUSS INTC
29-0	pru<n>_r31_status[29:0]	Status inputs from primary input via Enhanced GPI port

7.4.4.2.2.2 Event Interface Mapping (R31): PRU System Events

This PRU Event Interface directly feeds pulsed event information out of the PRU's internal ALU. These events are exported out of the PRUSS and need to be connected to the system interrupt controller at the SoC level. The event interface can be used by the firmware to create software interrupts from the PRU to the Host processor.

Copyright © 2024 Texas Instruments Incorporated

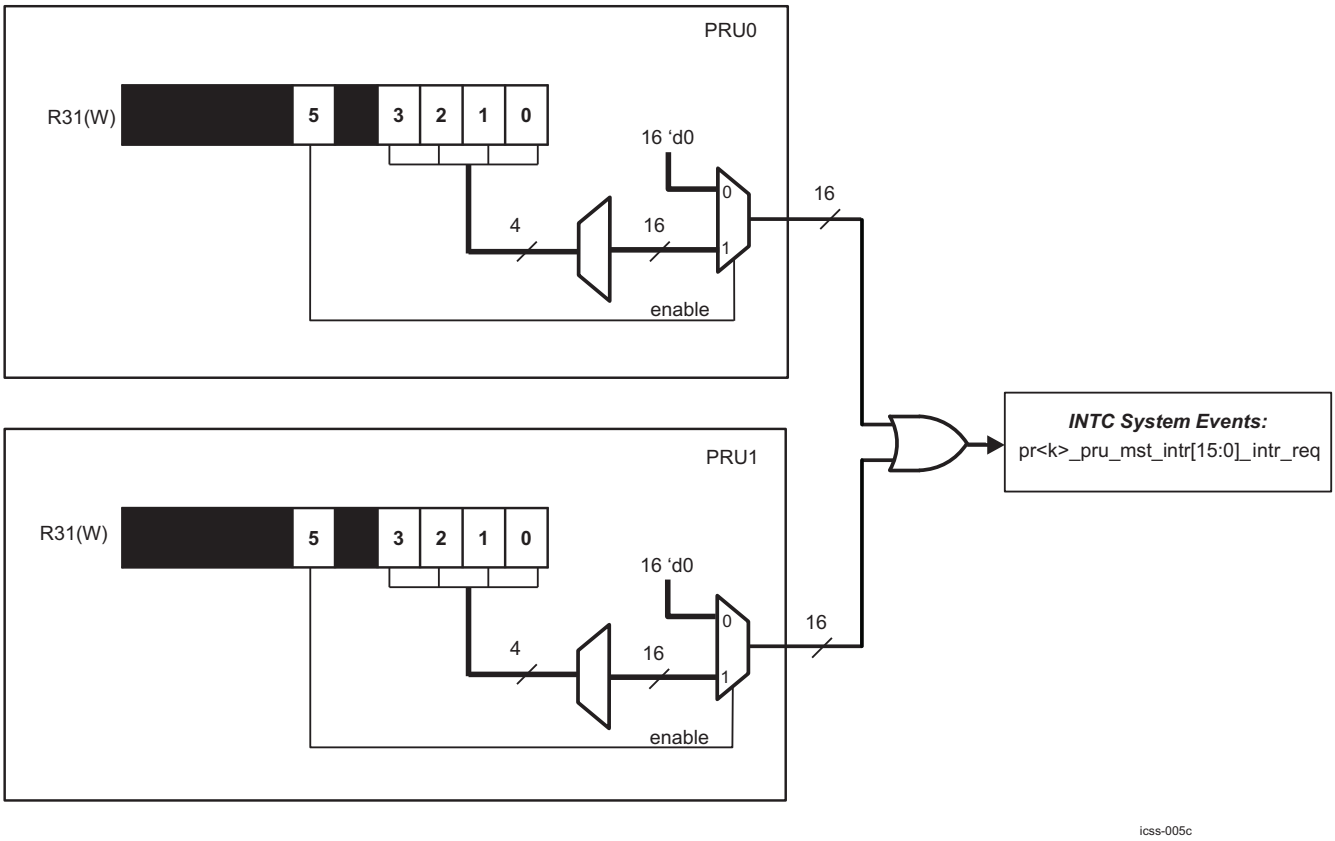

Figure 7-22. Event Interface Mapping (R31)

Table 7-39. Event Interface Mapping (R31) Field Descriptions

Bit	Field	Description
31-6	Reserved	
5	pru<n>_r31_vec_valid	Valid strobe for vector output
4	Reserved	
3-0	pru<n>_r31_vec[3:0]	Vector output

Simultaneously writing a '1' to pru<n>_r31_vec_valid (R31 bit 5) and a channel number from 0 to 15 to pru<n>_r31_vec[3:0] (R31 bits 3-0) creates a pulse on the output of the corresponding pr<k>_pru_mst_intr[x]_intr_req INTC system event. For example, writing '100000' will generate a pulse on prk_pru_mst_intr[0]_intr_req, writing '100001' will generate a pulse on prk_pru_mst_intr[1]_intr_req, and so on to where writing '101111' will generate a pulse on prk_pru_mst_intr[15]_intr_req and writing '0xxxxx' will not generate any system event pulses. The output values from both PRU cores in a subsystem are ORed together.

The output channels 0-15 are connected to the INTC system events 16-31, respectively. This allows the PRU to assert one of the system events 16-31 by writing to its own R31 register. The system event is used to either post a completion event to one of the host CPUs (Arm) or to signal the other PRU. The host to be signaled is determined by the system interrupt to interrupt channel mapping (programmable). The 16 events are named as prk_pru_mst_intr<15:0>_intr_req. See the *PRUSS Interrupt Requests Mapping,* in the section*PRUSS Local Interrupt Controller*, for more details.

7.4.4.2.2.3 General-Purpose Inputs (R31): Enhanced PRU GP Module

The PRUSS implements an enhanced General Purpose Input/Output (GPIO) module with SCU that supports the following general-purpose input modes: direct input, 16-bit parallel capture, 28-bit serial shift in, and MII_RT.

Copyright © 2024 Texas Instruments Incorporated

Register R31 serves as an interface with the general-purpose inputs. Table 7-40 describes the input modes in detail.

Note

Each PRU core can only be configured for one GPI mode at a time. Each mode uses the same R31 signals and internal register bits for different purposes. A summary is found in Table 7-41.

Note

The PRU_ICSSM_GPCFG0 register, bitfield [29-26] PR1_PRU0_GP_MUX_SEL (PRU0 or PRU1) in the PRUSS CFG register space needs to be set to 0h for GP mode. For a given PRU core, the following IO modes are mutually exclusive: GP mode, Sigma Delta mode, and 3 channel Peripheral I/F mode.

Table 7-40. PRU R31 (GPI) Modes

Mode	Function	Configuration
Direct input	GPI[19:0] feeds directly into the PRU R31	Default state
16-bit parallel capture	DATAIN[0:15] is captured by the posedge or negedge of CLOCKIN	• Enabled by PRU_ICSSM_GPCFG0 register (PRU0 or PRU1) • CLOCKIN edge selected by PRU_ICSSM_GPCFG0 register
28-bit shift in	DATAIN is sampled and shifted into a 28-bit shift register. • Shift Counter (Cnt_16) feature is mapped to pru<n>_r31_status[28]. • SB (Start Bit detection) feature is mapped to pru<n>_r31_status[29]	• Enabled and disabled by PRU_ICSSM_GPECFG0 register (PRU0 or PRU1) • Cnt_16 is self clearing and is connected to the PRU INTC • Start Bit (SB) is cleared by PRU_ICSSM_GPECFG0 register • Start Bit value (0h or 1h) selected by PRU_ICSSM_GPECFG0 register
PERIF	The 3 channel Peripheral Interface supports functionality for operations utilized the EnDat 2.2 and BiSS protocols.	Enabled by PRU_ICSSM_GPCFG0[1-0] PRU0_GPI_MODE register (value: 1h), where n = 0 or 1
MII_RT	mii_rt_r31_status [29:0] internally driven by the MII_RT module	Enabled by PRU_ICSSM_GPCFG0[1-0] PRUn_GPI_MODE register (value: 2h), where n = 0 or 1
Sigma Delta	Up to nine channels of concurrent counting with clock source configuration for each channel.	Enabled by PRU_ICSSM_GPCFG0[1-0] PRUn_GPI_MODE register (value: 3h), where n = 0 or 1

PR<k>_PRU<n>_GPI19	GPI19					

(1) These pins are also used for Sigma Delta or Peripheral I/F mode.

7.4.4.2.2.3.1 PRU EGPIs Direct Input

The pru<n>_r31_status[0:19] bits of the internal PRU register file are mapped to device-level, general purpose input pins (PRU0_GPI[0:19]). In GPI Direct Input mode, PRU0_GPI[0:19] feeds directly to pru<n>_r31_status[0:19].

Each PRU of the PRUSS has a separate mapping to device input signals - PRn_PRU0_GPI[19:0] for the PRU0 core and PRn_PRU1_GPI[19:0] for the PRU1 core. There are general purpose inputs in total. For more details, refer also to the *PRUSS-M Environment*. See the device's system reference guide or datasheet for device specific pin mapping.

Note

The following PRU IO are not pinned out at the device level: PR0_PRU0_GPIO[7,17,18,19]

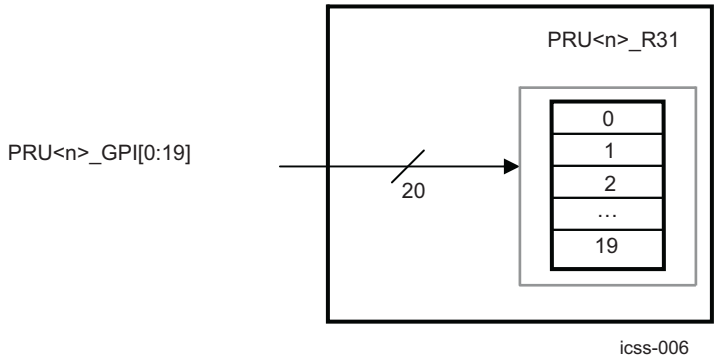

Figure 7-23. PRU R31 (EGPI) Direct Input Mode Block Diagram

Copyright © 2024 Texas Instruments Incorporated

7.4.4.2.2.3.2 PRU EGPIs 16-Bit Parallel Capture

The pru<n>_r31_status[0:15] and pru<n>_r31_status[16] bits of the internal PRU register file mapped to device-level, general purpose input pins (PRU0_DATAIN [0:15] and PRU0_CLOCKIN, respectively). PRU0_CLOCKIN is designated for an external strobe clock, and is used to capture PRU0_DATAIN [0:15].

The PRU<n>_DATAIN can be captured either by the positive or the negative edge of PRU<n>_CLOCK, programmable through the PRUSS CFG register space. If the clocking is configured through the PRUSS CFG register to be positive, then it will equal PRU<n>_CLOCK; however, if the clocking is configured to be negative, then it will equal PRU<n>_CLOCK inverted.

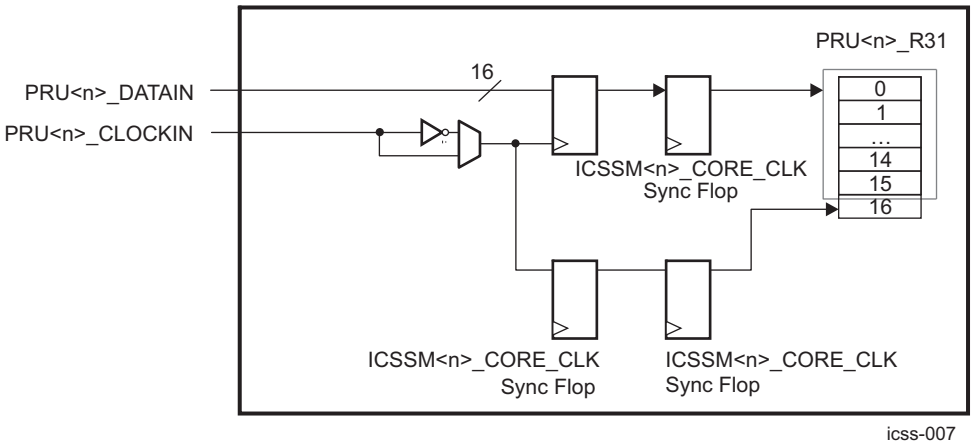

Figure 7-24. PRU R31 (EGPI) 16-Bit Parallel Capture Mode Block Diagram

7.4.4.2.2.3.3 PRU EGPIs 28-Bit Shift In

In 28-bit shift in mode, the device-level, general-purpose input pin PRU<n>_DATAIN is sampled and shifted into a 28-bit shift register on an internal clock pulse. The register fills in LSB order (from bit 0 to 27) and then overflows into a bit bucket. The 28-bit register is mapped to pru<n>_r31_status[0:27] and can be cleared in software through the PRU_ICSS_GPCFG0[13] PRU0_GPI_SB register (PRU0 or PRU1).

Note that by default, the PRU will continually capture and shift the DATAIN input when the GPI mode has been set. However, clearing the PRU_ICSS_GPCFG0[1] PRU0_GPI_SHIFT_EN bit will freeze the shift operation.

The shift rate is controlled by the effective divisor of two cascaded dividers applied to the PRU-ICSS<n>_CORE_CLK clock (). These cascaded dividers can each be configured through the PRUSS CFG register space to a value of {1, 1.5, …, 16}. Table 7-42 shows sample effective clock values and the divisor values that can be used to generate these clocks.

Table 7-42. PRU EGPIs Effective Clock Values

Generated clock	PRU0_GPI_DIV0	PRU0_GPI_DIV1
8-MHz	12.5 (17h)	2 (02h)
10-MHz	10 (12h)	2 (02h)
16-MHz	16 (1Eh)	1 (00h)
20-MHz	10 (12h)	1 (00h)

The 28-bit shift mode also supports the following features:

- SB (Start Bit detection) is mapped to pru<n>_r31_status[29] and is set when the first 1 (default) or 0 is captured on PRU<n>_DATAIN. The Start Bit value (1 or 0) is configured through the PRU_ICSS_GPECFG0[0] PRU0_GPI_SB_P bit (PRU0 or PRU1). The SB flag in pru<n>_r31_status[29] is cleared in software through the PRUSS CFG register space.

Copyright © 2024 Texas Instruments Incorporated

- Cnt_16 (Shift Counter) is mapped to pru<n>_r31_status[28] and is set on every 16 shift clock samples after the Start Bit has been received. CNT_16 is self clearing and is connected to the local PRUSS INTC. See the *PRUSS Local Interrupt Controller* for more details.
- The PRU_ICSS_GPECFG0[1] PRU0_GPI_SHIFT_EN bit can stop or freeze the current shift operation and disable the search for a new Start Bit, if an SB event has not occurred.

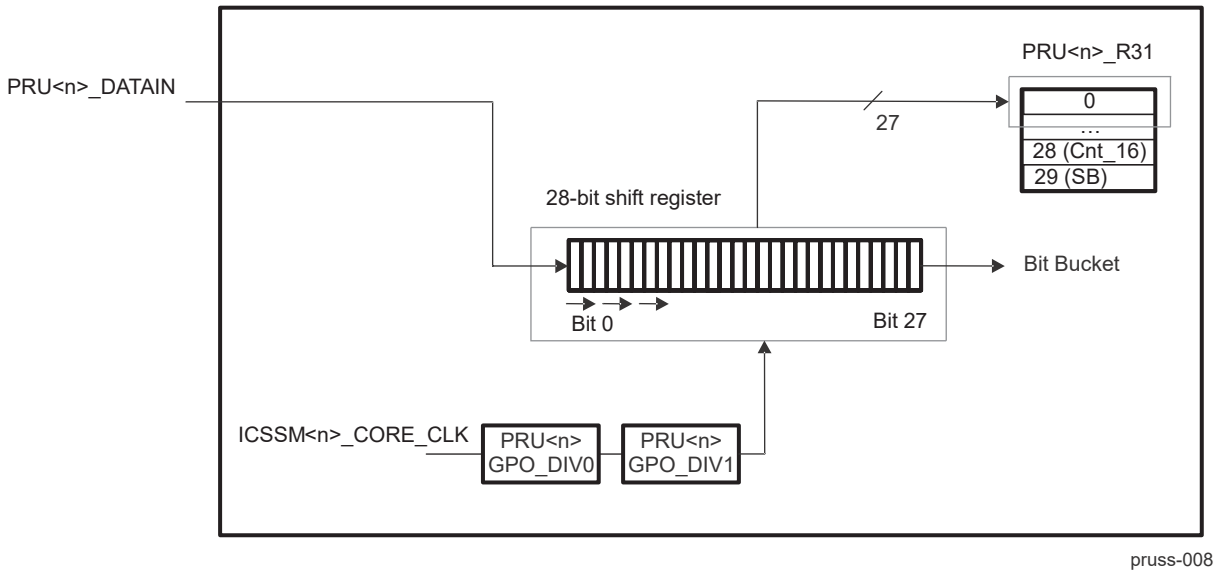

Figure 7-25. PRU R31 (EGPI) 28-Bit Shift Mode

7.4.4.2.2.3.3.1 PRU EGPI Programming Model

Follow this steps to configure the PRU EGPI in 28-bit shift input mode:

1. Clear PRU_ICSS_GPECFG0[1] PRU0_GPI_SHIFT_EN bit (PRU0 or PRU1)
2. Clear/Set PRU_ICSS_GPECFG0[0] PRU0_GPI_SB_P bit (PRU0 or PRU1)
3. Clear Start Bit by writing 1h to PRU_ICSS_GPCFG0[13] PRU0_GPI_SB bit
4. Program the dividers through:
   PRU_ICSS_GPCFG0[24-20] PRU0_GPO_DIV1 bit (PRU0 or PRU1)
   PRU_ICSS_GPCFG0[19-15] PRU0_GPO_DIV0 bit (PRU0 or PRU1)
5. Enable Shift Input Mode by writing to PRU_ICSS_GPECFG0[1] PRU0_GPI_SHIFT_EN bit

7.4.4.2.2.3.4 General-Purpose Outputs (R30): Enhanced PRU GP Module

The PRUSS implements an enhanced General Purpose Input/Output (GPIO) module that supports two general-purpose output modes: direct output and shift out.

Table 7-43 describes these modes in detail.

Note

Each PRU core can only be configured for one GPO mode at a time. Each mode uses the same R30 signals and internal register bits for different purposes. A summary is found in Table 7-43.

Note

The PRU_ICSS_GPCFG0 register, bitfield [29-26] PR1_PRU0_GP_MUX_SEL (PRU0 or PRU1) in the PRUSS CFG register space needs to be set to 0h for GP mode. For a given PRU core, the following IO modes are mutually exclusive: GP mode, Sigma Delta mode, and 3 channel Peripheral I/F mode.

Copyright © 2024 Texas Instruments Incorporated

Table 7-43. PRU R30 (EGPO) Output Mode

Mode	Function	Configuration
Direct output	pru<n>_r30[19:0] feeds directly to GPO[19:0]	Default state
Shift out	• pru<n>_r30[0] is shifted out on DATAOUT on every rising edge of pru<n>_r30[1] (CLOCKOUT). • LOAD_GPO_SH0 (Load Shadow Register 0) is mapped to pru<n>_r30[29]. • LOAD_GPO_SH1 (Load Shadow Register 1) is mapped to pru<n>_r30[30]. • ENABLE_SHIFT is mapped to pru<n>_r30[31].	Enabled by PRU_ICSS_GPCFG0 register (PRU0 or PRU1) Free Running Clock or Fixed Clock Count Mode selected by PRU_ICSS_GPECFG0 register.

Table 7-44. GPO Mode Descriptions

Pad Names at Device Level (1)	GPO Modes	
	Direct output	Shift out
PR<k>_PRU<n>_GPO0	GPO0	DATAOUT
PR<k>_PRU<n>_GPO1	GPO1	CLOCKOUT

PR<k>_PRU<n>_GPO13	GPO13	
PR<k>_PRU<n>_GPO14	GPO14	
PR<k>_PRU<n>_GPO15	GPO15	
PR<k>_PRU<n>_GPO16	GPO16	
PR<k>_PRU<n>_GPO17	GPO17	
PR<k>_PRU<n>_GPO18	GPO18	
PR<k>_PRU<n>_GPO19	GPO19	

(1) These pins are also used for Sigma Delta or Peripheral I/F mode.

7.4.4.2.2.3.4.1 PRU EGPOs Direct Output

The PRU0_r30 [19:0] bits of the internal PRU register files are mapped to device-level, general-purpose output pins (PRU0_GPO[0:19]). In GPO Direct Output mode, PRU0_r30[0:19] feed directly to PRU0_GPO[0:19]. Each PRU of the PRUSS has a separate mapping to pins, so that there are 40 total general-purpose outputs from the PRUSS. See the device's system reference guide or datasheet for device-specific pin mapping.

Copyright © 2024 Texas Instruments Incorporated

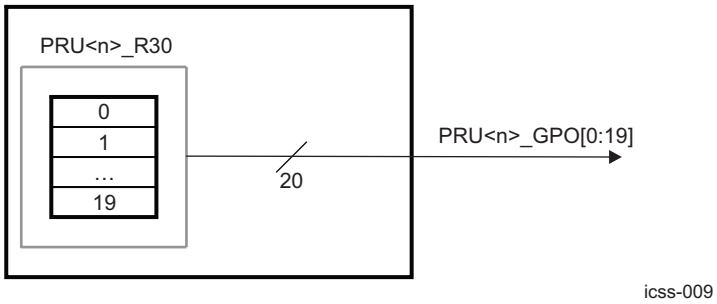

Figure 7-26. PRU R30 (EGPO) Direct Output Mode Block Diagram

7.4.4.2.2.3.4.2 PRU EGPO Shift Out

In shift out mode, data is shifted out of PRU0_r30[0] (PRU0_DATAOUT) on every rising edge of PRU0_r30[1] (PRU0_CLOCK). The shift rate is controlled by the effective divisor of two cascaded dividers applied to the PRUSS<n>_CORE_CLK clock (). These cascaded dividers can each be configured through the PRUSS CFG register space to a value of {1, 1.5, …, 16}. Table 7-45 shows sample effective clock values and the divisor values that can be used to generate these clocks. Note that shift out mode supports two clocking submodes - Free Running Clock Mode (default) and Fixed Clock Count Mode. The clocking submode is selected through PRU_ICSS_GPECFG0[5] PRU0_GPO_SHIFT_CLK_FREE. In Free Running Clock Mode, PRU0_CLOCKOUT is a free running clock that starts when the PRU GPO mode is set to shift out mode.

Table 7-45. Effective Clock Values

Generated Clock	PRU0_GPO_DIV0	PRU0_GPO_DIV1
8 MHz	12.5 (17h)	2 (02h)
10 MHz	10 (12h)	2 (02h)
16 MHz	16 (1Eh)	1 (00h)
20 MHz	10 (12h)	1 (00h)

Shift out mode uses two 16-bit shadow registers (GPO_SH0 and GPO_SH1) to support ping-pong buffers. Each shadow register has independent load controls programmable through PRU0_r30[29:30] (PRU0_LOAD_GPO_SH[0:1]). While PRU0_LOAD_GPO_SH[0:1] is set, the contents of PRU<n>_R30[0:15] are loaded into GPO_SH0 and GPO_SH1 shadow registers.

The data shift will start from the LSB or MSB of GPO_SH0 when PRU<n>_R30[31] (PRU0_ENABLE_SHIFT) is set. The LSB or MSB setting is configurable through PRU_ICSS_GPECFG0[4] PRU0_GPO_SHIFT_SWAP. Note that if no new data is loaded into GPO_SH0/GPO_SH1 after shift operation, the shift operation will continue looping and shifting out the pre-loaded data.

For Free Running Clock Mode, the shift operation will continue until PRU0_ENABLE_SHIFT is cleared. When PRU0_ENABLE_SHIFT is cleared, the shift operation will finish shifting out the current shadow register, stop, and then reset.

For Fixed Clock Count Mode, the number of data bits to be shifted out is defined by PRU_ICSS_GPECFG0[15-8] PRU0_GPO_SHIFT_CNT. PRU<n>_CLOCKOUT will stop either high or low with the last data bit. The last data bit will remain persistent. However, the clock stop state is configurable through PRU_ICSS_GPECFG0[16] PRU0_GPO_SHIFT_CLK_HIGH.

The source of PR<k>_PRU<n>_GPO[2:15] is configurable by PRU_ICSS_GPECFG0[6] PRU0_GPO_SHIFT_GP_EN. By default, if any device-level pins mapped to PRU<n>_R30[2-15] are configured for the PR<k>_PRU<n>_GPO[2:15] pinmux mode, then these pins will reflect the shadow register value written to PRU<n>_R30. Any pin configured for a different pinmux setting will not reflect the shadow register value written to PRU<n>_R30. However, setting PRU_ICSS_GPECFG0[6] PRU0_GPO_SHIFT_GP_EN = 1h allows PRU<n>_R30[2:15] to be controlled by PRU<n>_R30_SHADOW[2-15], which is updated by PRU<n>_R30[2:15] when PRU<n>_R30[28] = 1h.

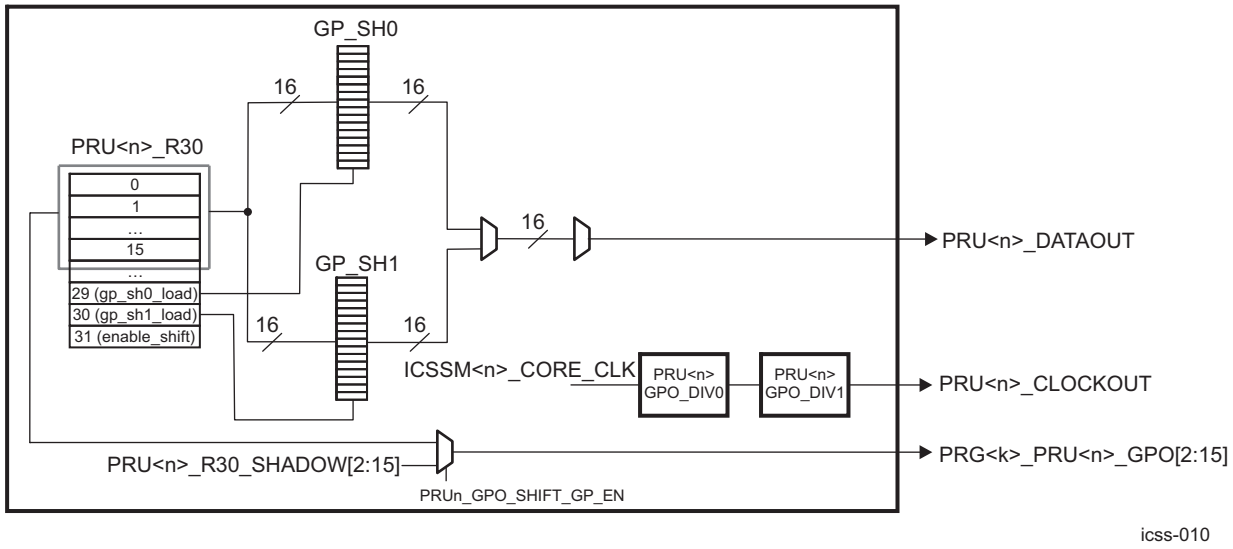

Figure 7-27. PRU R30 (GPO) Shift Out Mode Block Diagram

7.4.4.2.2.3.4.2.1 PRU EGPO Programming Model

After the PRU is intilized, the software should only enable Shift Out Mode configuration per intilization.

7.4.4.2.2.3.5 Sigma Delta (SD) Decimation Filtering

Sigma-delta Sinc filtering is achieved by the combination of PRU hardware and firmware. PRU hardware provides hardware integrators that do the accumulation part of Sinc filtering, while the differentiation part is done in firmware.

The integrator serves to count the number of 1's per clock event. Each channel has three cascaded counters, which are the accumulators for the Sinc3 filter. Each counter is 28 bits, giving a maximum count of 268,435,456. Each channel has a free running rollover clock counter. This sample counter updates the count value on the effective clock event for that channel. Each channel also contains a programmable counter compare block, and the compare register has a size of 8 bits. However, the minimum value is 4 and maximum value is 256 due to the 28-bit accumulator. Once sample counter compare value is reached, the shadow register copy is updated and the shadow register copy flag is set.

Features of the integrators in PRUs SD Demodulator:

- Up to 9 channels concurrent counting
- Software can read all 3 stages accumulators
- Flexible clock source configuration for each channel; option of independent clock source for each channel or one clock source for three channels
- Programmable, 8-bit sample counter compare register; used to set the OSR of Sinc filter
- Three 28-bit cascaded counters per channel for accumulation, only Sinc3 and Sinc2 modes supported
- Common channel enable (all channels are active or none are active)
- Fast 1 and 0 min/max count sliding programmable window for each of the 9 channels

7.4.4.2.2.3.5.1 Sigma Delta Block Diagram and Signals

The Sigma Delta's I/Os are multiplexed with the PRU GPI/GPO signals, as shown in Table 7-46.

Note: The PR<k>_PRU<n>_GP_MUX_SEL bitfield in the PRU_ICSS_GPCFG0 register (where k = 0 or 1 and n = 0 or 1) must be set to 3h for configure the GPI/GPO signals for SD mode.

Table 7-46. PRU GPI Signals and Configurations for Sigma Delta

Signal Names at Device Level (1)	Sigma Delta (SD) Mode	Function
PR<k>_PRU<n>_GPI0	SD0_CLK	SD demodulator clock channel 0

PR<k>_PRU<n>_GPI17	SD8_D	SD demodulator data channel 8
PR<k>_PRU<n>_GPI18	-	
PR<k>_PRU<n>_GPI19	-	

(1) Note: These signals are shared with the GP and Peripheral I/Fs. To configure for Sigma Delta, PRU_ICSS_GPCFG0[29-26] PR1_PRU0_GP_MUX_SEL (where k = 0 or 1 and n = 0 or 1) needs to be set to 3h for SD mode.

The PR<k>_PRU0_GPI1 signal (muxed with SD0_D) can be used as SD_CLKOUT when PRUSS generates clock. This is a trade-off as PRU application will lose one SD channel. SD_CLKOUT needs to go through a clock generator chip if driving multiple sigma delta modulators and also be looped back into PRUSS as SD_CLKIN, typically pru_gpi16.

Note: To output the SD clock on PR<k>_PRU0_GPO1, this device requires that the PRU core be configured for both SD and shift out mode (PRU_ICSS_GPCFG0[29-26] PR1_PRU0_GP_MUX_SEL = 3h and PRU_ICSS_GPCFG0[14] PRU<n>_GPO_MODE = 1h). Be sure to configure the shift out mode's clock divisors before enabling shift out mode (PRU_ICSS_GPCFG0[14] PRU<n>_GPO_MODE = 1h). Additionally, the PRUSS, PRU0 SD clock is routed to both PR0_PRU0_GPO1 and PR0_PRU1_GPO1. Figure 7-28 shows a block diagram of the Sigma Delta implementation. Full description of the PRU R30 and R31 registers are shown in Table 7-48 and Table 7-49.

Copyright © 2024 Texas Instruments Incorporated

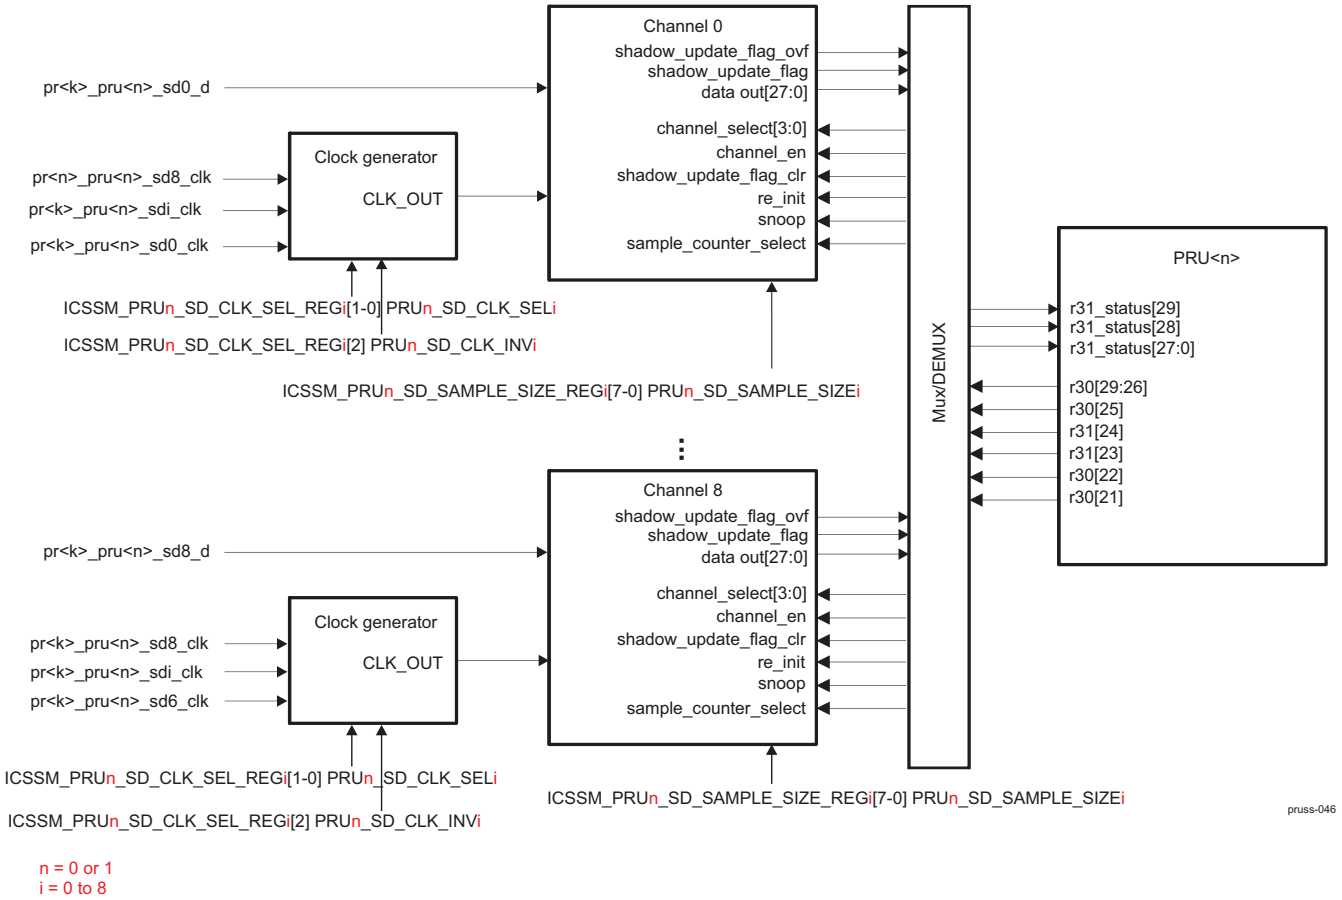

Figure 7-28. Sigma Delta Block Diagram

Note: Each channel can independently be configured to use one of three external clock sources. Table 7-47 shows the clock source options, selectable through PRU_ICSS_PRU0_SD_CLK_SELi[1-0] PRU0_SD_CLK_SELi (where n = 0 or 1 and i = 0 to 8).

Table 7-47. Sigma Delta External Clock Sources

PRU0_SD_CLK_SELi value	Clock Source
0	pr<k>_pru<n>_sd8_clk
1	pr<k>_pru<n>_sd<i>_clk
2	pr<k>_pru<n>_sd0_clk for sd0, sd1, and sd2; pr<k>_pru<n>_sd3_clk for sd3, sd4, and sd5; pr<k>_pru<n>_sd6_clk for sd6, sd7, and sd8

7.4.4.2.2.3.5.2 PRU R30 / R31 Interface

The PRU uses the R30 and R31 registers to interface with the Sigma Delta interface. Table 7-48 and Table 7-49 shows the R31 and R30 interface for the Sigma Delta mode. Note that only the parameters and data for one channel can be viewed at a time. The channel to be viewed is determined by the r30[29-26] (channel_select).

Table 7-48. Sigma Delta PRU Registers: R31

Bits	Field Name	Description
31-30	Reserved	
29	shadow_update_flag_ovf	Shadow update flag overflow, set when over sample count equals over sample size and shadow_update_flag is still set. Set bit R31[24] to clear the flag.
28	shadow_update_flag	Shadow update flag, set when over sample count equals over sample size and shadow_update_flag is still set. Set bit R31[24] to clear the flag.

Copyright © 2024 Texas Instruments Incorporated

Table 7-48. Sigma Delta PRU Registers: R31 (continued)

Bits	Field Name	Description
27-0	data_out[27-0]/ shadow_update_flag_clr (R31[24]) / re_init (R31[23])	data_out[27] (read): most-significant bit of sample data shadow_update_flag_clr (write): re_init (write): Set to reset all counters, flags, and shadow copy. Updates over_sample_size based on the current PRU_ICSS_PRU0_SD_SAMPLE_SIZEi[7-0] register (where n = 0 or 1 and i = 0 to 8) on the selected channel. shadow_update_flag_clr (write): Set to clear shadow_update_flag and shadow_update_flag_ovf (if set).

Table 7-49. Sigma Delta PRU Registers: R30

Bits	Field Name	Description
31-30	Reserved	
29-26	channel_select[3-0]	Channel select 0h: Channel 0 ... 8h: Channel 8 9h: Reserved ... Fh: Reserved
25	channel_en	Global Channel enable (effects all 9 channels). 0h: All channels disabled. Counters/flags are cleared. 1h: All channels enabled.
24-23	Reserved	
22	snoop	Enable snoop (i.e. fetch data) on the selected channel. 0h: acc1/acc2/acc3 shadow copy 1h: current acc1/acc2/acc3
21	sample_counter_select	Read sample counter. 0h: Not selected 1h: Sample count selected
20-0	Reserved	

The PRUSS CFG register space has additional registers for controlling the SD demodulator module:

- PRU_ICSS_PRU0_SD_CLK_SELi[5-4] PRU0_SD_ACC_SELi (where n = 0 or 1, i = 0 to 8) - Selects accumulator 1, 2 or 3 as source (acc1/acc2/acc3).
- PRU_ICSS_PRU0_SD_CLK_SELi[2] PRU0_SD_CLK_INVi (where n = 0 or 1, i = 0 to 8) - Inverts clock.
- PRU_ICSS_PRU0_SD_CLK_SELi[1-0] PRU0_SD_CLK_SELi (where n = 0 or 1, i = 0 to 8) - Selects the clock source.
- PRU_ICSS_PRU0_SD_SAMPLE_SIZEi[7-0] PRU0_SD_SAMPLE_SIZEi (where n = 0 or 1, i = 0 to 8) - Selects number of samples to read before giving output.

7.4.4.2.2.3.5.3 Sigma Delta Description

Figure 7-29 shows a block diagram of the Sigma Delta hardware integrators and integration with the PRU R30 / R31 interface for a single channel.

Copyright © 2024 Texas Instruments Incorporated

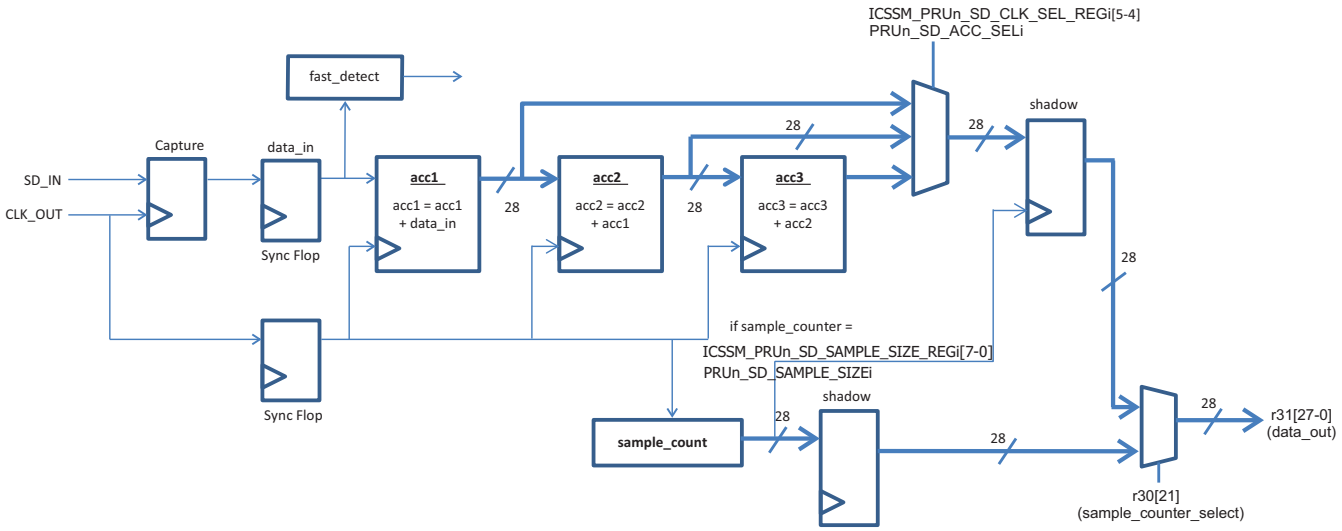

Figure 7-29. Sigma Delta Hardware Integrators Block Diagram (snoop = 0)

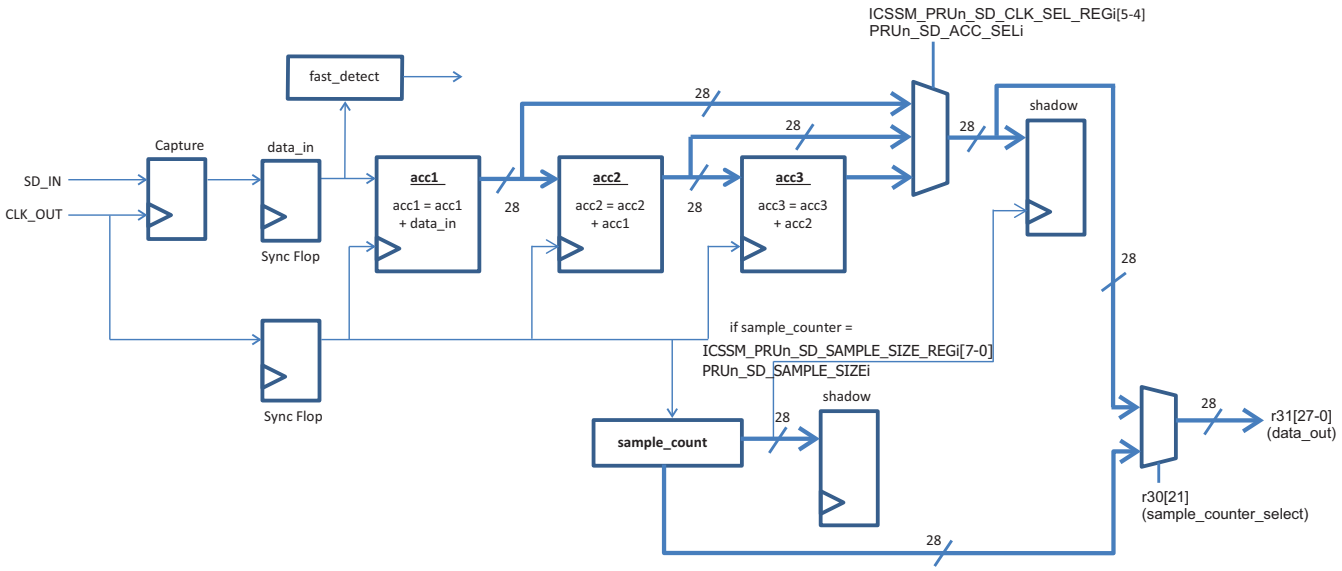

Figure 7-30. Sigma Delta Hardware Integrators Block Diagram (snoop = 1)

The three accumulators (acc1-acc3) for each channel are simple 28 bit adders. The input for acc1 is 1-bit, while the inputs for acc2 and acc3 are 28-bits. On each positive edge of the CLK_OUT, all three 28-bit counters (acc1-acc3) and the sample counter for each channel will get updated as follows:

```
acc1 = acc1 + data_in
acc2 = acc2 + acc1
acc3 = acc3 + acc2
sample_count = sample_count + 1
```

Each accumulator will rollover at 0xFF_FFFF. For example if acc2 = 0x10 and acc3 = 0xFF_FFFF, then acc3 will update to 0x00_0000F on the next clock event. Sample counter will rollover when it equals the defined sample size (PRU_ICSS_PRU0_SD_SAMPLE_SIZEi[7-0] PRU0_SD_SAMPLE_SIZEi).

Note that while the channels are not enabled, no operations are performed and all flags and counters are cleared. If a new sample size is to be loaded, the PRU firmware should assert re_init (r31[23]), and all stored count values are cleared to 0.

Copyright © 2024 Texas Instruments Incorporated

Fast detect block is used to detect fast changes in the amount of ones, presented in a programmable sliding window of 4 to 32 bits. The sliding window is controlled by PRU_ICSS_PRU0_SD_SAMPLE_SIZEi[10-8] PRU0_FD_WINDOW_SIZE_i bit field.

Fast detect must be enabled through the PRU_ICSS_PRU0_SD_SAMPLE_SIZEi[23] PRU0_FD_EN_i register before SD is enabled. It will start the compare after the first 32 sample clocks. Fast detect block will remain active until a re_init (r31[23]) is asserted.

The Sigma Delta interface has two status flags:

- Shadow update flag (r31[28])
- Shadow update flag overflow (r31[29])

When sample_counter equals the defined sample size (PRU_ICSS_PRU0_SD_SAMPLE_SIZEi[7-0] PRU0_SD_SAMPLE_SIZEi), then the acc1/acc2/acc3 shadow register copy will be updated, the shadow_update_flag (r31[28]) will be set, and sample_counter will rollover to 0. The PRU firmware can clear this flag by writing '1' to shadow_update_flag_clr (r31[28]). If sample_count equals the defined sample size and the shadow_update_flag is still set, then shadow_update_flag_ovf (r31[29]) will be set. Similarly, the PRU firmware can clear this flag by writing '1' to shadow_update_flag_ovf_clr (r31[29]). Note that the clear operation for both flags has a higher priority than the set event.

The PRU firmware can monitor the acc2/acc3 and sample_counter values through data_out[27-0] (r31[27-0]). Table 7-50 shows the configuration options for data_out[27-0].

Table 7-50. Data_out[27-0] Configuration Options

snoop (r30[22])	sample_counter_select (r30[21])	data_out (r31[27-0])
0	0	Reads acc1/acc2/acc3 shadow register copy. See Figure 7-29 *Sigma Delta Hardware Integrators Block Diagram (snoop = 0).*
1	0	Reads acc1/acc2/acc3 directly. See Figure 7-30 *Sigma Delta Hardware Integrators Block Diagram (snoop = 1).*
0	1	Reads sample_counter shadow register copy. See Figure 7-29 *Sigma Delta Hardware Integrators Block Diagram (snoop = 0).*
1	1	Reads sample_counter directly. See Figure 7-30 *Sigma Delta Hardware Integrators Block Diagram (snoop = 1).*

7.4.4.2.2.3.5.4 Sigma Delta Basic Programming Example

The following programming example assumes that the PRU is configured for Sigma Delta Mode (**PRU_ICSS_GPCFG0**[29-26] PR1_PRU<n>_GP_MUX_SEL = 3h).

1. Configure clock sources, accumulator source, and sample size:
   a. PRU_ICSS_PRU0_SD_CLK_SELi[1-0] PRU0_SD_CLK_SELi (where n = 0 or 1, i = 0 to 8) for clock source
   b. PRU_ICSS_PRU0_SD_CLK_SELi[2] PRU0_SD_CLK_INVi (where n = 0 or 1, i = 0 to 8) for clock polarity
   c. PRU_ICSS_PRU0_SD_CLK_SELi[5-4] PRU0_SD_ACC_SELi (where n = 0 or 1, i = 0 to 8) - for accumulator source (acc1/acc2/acc3)
   d. PRU_ICSS_PRUSS_SD_PRU0_SAMPLE_SIZEi[7-0] PRU0_SD_SAMPLE_SIZE for sample size
2. Reinitialize all channels whose sample size was configured
   a. Select channel by writing to channel_select (r30[29-26])
   b. Delay at least 1 PRU cycle before executing re_int in step 2c.
   c. Reinitialize selected channel by writing to re_init (r31[23])
   d. Repeat steps 2a & 2b for all configured channels
3. Enable all channels by writing '1' to channel_en (r30[25])
4. Select channel by writing to channel_select (r30[29-26])

Copyright © 2024 Texas Instruments Incorporated

a. Poll shadow_update_flag (r31[28]) to detect when acc1/acc2/acc3 shadow register copy data is ready to be read
b. Delay at least 1 PRU cycle before polling shadow_update_flag in Step 4c.
c. Read data_out[27-0] (r31[27-0])
d. Clear shadow_update_flag by writing '1' to r31[24]

5. Repeat step 4 for new channel

7.4.4.2.2.3.6 Three Channel Peripheral Interface

The 3 channel Peripheral Interface supports functionality for operations utilizing the EnDat 2.2 and BiSS protocols. The 3 channel Peripheral Interface supports both 2 wire and 4 wire serial RS-485 communication. The following table shows the supported encoder protocols for the PRU-ICSS.

Table 7-51. Three Channel Peripheral Interface Supported Encoder Protocols

Encoder Protocol	Number of wire in RS-485 Communication
EnDat 2.2	4 wire
BiSS	4 wire
HDSL	2 wire
Tamagawa	2 wire

This module supports the following features:

- 3 channels with baud range from 100 kHz to 16 MHz
- PRU_ICSS_UART_CLK (default) or PRU_ICSS_ICLK controller clock is an input to independent div16fr clock dividers to produce a 1X clock (PERIF<m>_CLK) and oversampling clock
- Half-duplex (TX and RX are not supported concurrently)
- TX FIFO size of 32 bits
- RX FIFO size of 4 bits
- Configurable shift size/oversampling on RX
- Optional RX frame size auto shut off
- Programmable HW delay 1 (wire delay, controlling when the clock signal is first driven low) and delay 2 (tst delay, controlling when the clock signal is first driven high) on TX operation
- Optional programmable TX termination
- Individual TX channel start trigger (tx_channel_go) or simultaneous TX start trigger for all channels (tx_global_go)
- Flexible HW assisted clock output generation to allow free running, stop high and stop low (after last RX data), or stop high (after last TX data) operation with optional software clock override feature
- Optional SW direct snoop of data input
- RX Start Bit of '1' or '0'

7.4.4.2.2.3.6.1 Peripheral Interface Block Diagram and Signal Configuration

The Peripheral Interface's I/Os are multiplexed with the PRU GPI/GPO signals, as shown in Table 7-52. The PR1_PRU<n>_GP_MUX_SEL bitfield in the PRU_ICSS_GPCFG0 register (PRU0 or PRU1) must be set to 1h for configure the GPI/GPO signals for Peripheral I/F mode.

(1) Usage of the Peripheral Interface signals are not restricted to only ENDAT interfaces.
(2) Note: These signals are shared with the GP, MII and Sigma Delta modes. To configure for Peripheral I/F, PRU_ICSS_GPCFG0[29-26] PR1_PRU0_GP_MUX_SEL needs to be set to 1h.
(3) Some devices may not pin out all 29 bits of R31 and all 32 bits of R30. For which pins are available on this device, see *PRUSS Environment*. See the device-specific Datasheet for device pin mapping.

A block diagram for the Peripheral I/F is included in Figure 7-31. As shown, each channel is composed of four I/Os:

- PERIF<m>_IN - RX input data
- PERIF<m>_CLK - Clock (CLK_OUT) generated by the 1x (or TX) clock. The default value is 1.

Copyright © 2024 Texas Instruments Incorporated

- PERIF<m>_OUT - TX output data. The default value is 0.
- PERIF<m>_OUT_EN - TX enable output (1 = TX mode, 0 = RX mode). The default value is 0. Note: This signal is auto controlled by hardware.

Figure 7-31. Peripheral I/F Block Diagram

7.4.4.2.2.3.6.2 PRU R30 and R31 Interface

The PRU uses the R30 and R31 registers to interface with the Peripheral I/F. Table 7-53 shows the R31 and R30 interface for the Peripheral I/F RX mode, and Table 7-54 shows the comparable interface for the TX mode.

Table 7-53. Peripheral I/F RX

Register	Bits	Field name	Description
R31	31-30	Reserved	PRU Host Interrupts 1/0 from local INTC
	29	ovf2	Overflow Flag for Channel 2. Write 1 to clear.
	28	ovf1	Overflow Flag for Channel 1. Write 1 to clear.
	27	ovf0	Overflow Flag for Channel 0. Write 1 to clear.
	26	val2	Valid Flag for Channel 2. Write 1 to clear.
	25	val1	Valid Flag for Channel 1. Write 1 to clear.
	24	val0	Valid Flag for Channel 0. Write 1 to clear.
	23-16	rx_data_out2	Oversampled Data Output for Channel 2. Note: These bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
	15-8	rx_data_out1	Oversampled Data Output for Channel 1. Note: These bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
	7:0	rx_data_out0	Oversampled Data Output for Channel 0. Note: These bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
R30	31-27	Reserved

Table 7-54. Peripheral I/F TX (continued)

Register	Bits	Field name	Description
	20-19	clk_mode	CLK_OUT mode. 0h: Free-running/stop-low. Clock will remain free-running until the receive module has received the number of bits indicated in rx_frame_counter and then the clock will stop low. 1h: Free-running/stop-high (default). Clock will remain free-running until the receive module has received the number of bits indicated in rx_frame_counter and then the clock will stop high. Note: This is the default/reset state, and a hardware reset or reinit will return clk_mode to this state. Note: The initial state of the clock will be high, but the clock will not start until TX GO event. 2h: Free-run. NOTE: You must do a reinit to get out of this clock mode then you can update clk_mode to a different mode. Also if you do multiple TX GO, the 2nd go should have tst_delay and wire_delay zero since the clock is free running after the first go. 3h: Stop high after transmit. Clock will run until the last TX bit is sent and stops high.
	18	Reserved	
	17-16	tx_ch_sel	TX channel select. 0h: Channel 0 1h: Channel 1 2h: Channel 2 3h: Reserved
	15-9	Reserved	
	7-0	tx_data	TX data for FIFO. Notes: FIFO transmits MSB first and is 32-bits deep. TX_FIFO_SWAP_BITS bit in the PRUSS CFG register space can be used to flip the load order of bits. The FIFO has 2 modes of operation: 1. Preload and Go. This should be done for EnDAT and frames less than 32-bits. 2. Continuous mode. This should be done for frames bigger than 32-bits. In continuous mode, software needs to keep up with the line rate and ensure that the FIFO is never empty. When the FIFO is at 2 byte level, software needs to load the next 2 bytes. If software waits till the end of the empty state, it is possible to get the TX into a bad state. The FIFO state can be recovered via re-init.

Note

The PRUSS CFG register space has additional registers for controlling the Peripheral I/F module.

7.4.4.2.2.3.6.3 Clock Generation

7.4.4.2.2.3.6.3.1 Configuration

The Peripheral I/F module has two source clock options, PRU_ICSS_UART_CLK (default) and PRU_ICSS_ICLK. There are two independent clock dividers (div16) for the 1x and oversampling (OS) clocks, and each clock divider is configurable by two cascading dividers:

- [31-16] PRU0_ED_TX_DIV_FACTOR and [15] PRU0_ED_TX_DIV_FACTOR_FRAC for the 1x clock
- [31-16] PRU0_ED_RX_DIV_FACTOR and [15] PRU0_ED_RX_DIV_FACTOR_FRAC for the OS clock

The 1x clock is output on the PERIF<m>_CLK signal. In TX mode, the output data is read from the TX FIFO at this 1x clock rate. The default value of this clock is high and the start and stop conditions for this clock are described in Section 4.4.2.2.3.6.3.2 *Clock Output Start Conditions* and Section 4.4.2.2.3.6.3.3 *Stop Conditions*.

In RX mode, the input data is sampled at the OS clock rate. Note: The OS clock rate divided by the 1x clock rate must equal [2-0] PRU0_ED_RX_SAMPLE_SIZE.

Example clock rates and divisor values relative to the 192-MHz PRU_ICSS_UART_CLK source are shown in Table 7-55.

Table 7-55. Clock Rate Examples for 192-MHz PRUSSn_UART_GFCLK Clock Source

TX_DIV_FACTOR	1x Clock	RX_DIV_FACTOR	RX_DIV_FACTOR_FRAC	OS Clock	Oversample Factor
12	16 MHz	1	1.5	128 MHz	8x

Table 7-55. Clock Rate Examples for 192-MHz PRUSSn_UART_GFCLK Clock Source (continued)

TX_DIV_FACTOR	1x Clock	RX_DIV_FACTOR	RX_DIV_FACTOR_FRAC	OS Clock	Oversample Factor
16	12 MHz	2	1	96 MHz	8x
24	8 MHz	3	1	64 MHz	8x
32	6 MHz	4	1	48 MHz	8x
48	4 MHz	6	1	32 MHz	8x
96	2 MHz	12	1	16 MHz	8x
192	1 MHz	24	1	8 MHz	8x

7.4.4.2.2.3.6.3.2 Clock Output Start Conditions

This section describes the configurable start conditions for the PERIF<m>_CLK. The software can completely control via PRU_ICSS_PRU0_ED_CHm_CFG0 when bit [29] PRU0_ED_CLK_OUT_OVR_ENm = 1h (where n = 0 or 1 and m = 0 to 2). By default however, the PRU hardware will control the clocks as described in the following sections.

7.4.4.2.2.3.6.3.2.1 TX Mode (RX_EN = 0)

In TX mode, the PERIF<m>_CLK begins after the firmware loads the TX FIFO and sets either r31[20] (tx_global_go) or r30[17-16] (tx_channel_go) to 1h. After the “go” bit is set, the delay1 (wire delay) compensation counter for each channel begins. After delay1 is complete, PERIF<m>_CLK is driven low and then the delay2 (tst) counter begins. After the delay2 counter expires, the PERIF<m>_CLK starts running (first low and then high). Therefore, first rising edge of PERIF<m>_CLK (measured from the go bit) = delay1 (tx wire delay) + delay2 (tst_counter delay) + half of the 1x clock frequency (since the clock starts low).

Figure 7-32 shows the start condition for TX mode. As shown in the figure, the default value of clock is high. The PRUSS CFG register space has additional registers for controlling the TX start timing delay values:

- Delay 1: PRU_ICSS_PRU0_ED_CHm_CFG0_REG[10-0] PRU0_ED_TX_WDLYm (where n = 0 or 1 and m = 0 to 2)
- Delay 2: PRU_ICSS_PRU0_ED_CHm_CFG1_REG[15-0] PRU0_ED_TST_DELAY_COUNTERm (where n = 0 or 1 and m = 0 to 2)

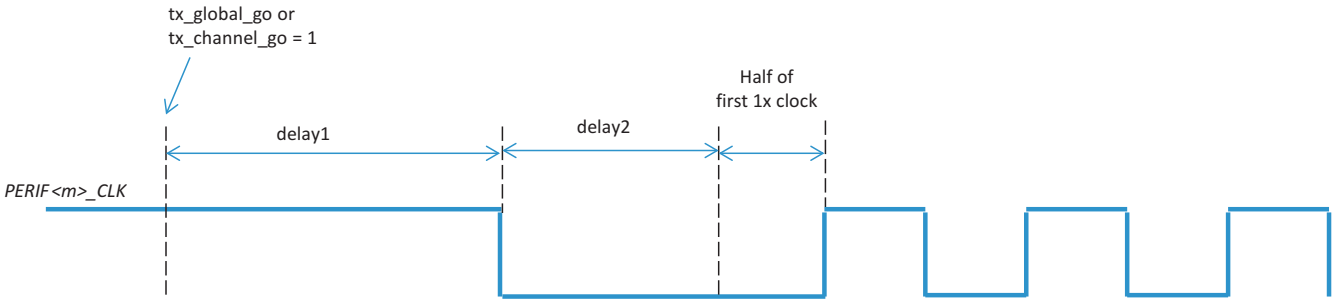

Figure 7-32. TX Mode Start Condition

7.4.4.2.2.3.6.3.2.2 RX Mode (RX_EN = 1)

In RX mode, the PERIF<m>_CLK will start running whenever the RX_EN is set. Note that the PRU firmware in this mode is responsible for any delay conditions.

The hardware can also auto-enable RX mode at the end of a TX transaction. The PRU_ICSS_PRU0_ED_CHm_CFG1_REG[31-16] PRU0_ED_RX_EN_COUNTERm (where n = 0 or 1 and m = 0 to 2) is used to program a delay between the last TX bit sent and when the RX_EN is set.

7.4.4.2.2.3.6.3.3 Stop Conditions

The r30[20-19] (clk_mode[1:0]) value determines the stop condition for PERIF<m>_CLK. There are 4 options available:

Copyright © 2024 Texas Instruments Incorporated

clk_mode_value	Description
0	Stop low on last RX frame
1	Stop high on last RX frame
2	Run continuously
3	Stop high on last TX bit

The last RX frame is configured by PRU_ICSS_PRU0_ED_CHm_CFG0_REG[27-16] PRU0_ED_RX_FRAME_SIZEm, and the last TX bit is configured by PRU_ICSS_PRU0_ED_CHm_CFG0_REG[15-11] PRU0_ED_TX_FRAME_SIZEm (where n = 0 or 1 and m = 0 to 2). Each stop condition is shown in Figure 7-33 through Figure 7-36.

7.4.4.2.2.3.6.4 Three Peripheral Mode Basic Programming Model

The following programming models assume that the PRU is configured for 3 Peripheral Mode (PRU_ICSS_GPCFG0[29-26] PR1_PRU0_GP_MUX_SEL = 1h).

7.4.4.2.2.3.6.4.1 Clock Generation

Follow these steps to configure Peripheral I/F clocks using the HW control of the clock:

1. Select TX and RX clock sources:
   a. PRU_ICSS_PRU0_ED_TX_CFG_REG[4] PRU0_ED_TX_CLK_SEL for the TX clock source
   b. PRU_ICSS_PRU0_ED_RX_CFG_REG[4] PRU0_ED_RX_CLK_SEL for the RX clock source
2. Configure the 1x (TX) clock frequency:
   a. Write Division Factor to PRU_ICSS_PRU0_ED_TX_CFG_REG[31-16] PRU0_ED_TX_DIV_FACTOR
   b. Write Fraction division factor to PRU_ICSS_PRU0_ED_TX_CFG_REGISTER[15] PRU0_ED_TX_DIV_FACTOR_FRAC
3. Configure the oversampling (RX) frequency and oversample size:
   a. Write Division Factor to PRU_ICSS_PRU0_ED_RX_CFG_REG[31-16] PRU0_ED_RX_DIV_FACTOR
   b. Write Fraction division factor to PRU_ICSS_PRU0_ED_RX_CFG_REG[15] PRU0_ED_RX_DIV_FACTOR_FRAC
   c. Write RX oversample size to PRU_ICSS_PRU0_ED_RX_CFG_REG[2-0] PRU0_ED_RX_SAMPLE_SIZE
4. Select the clk_mode to configure how the PERIF<m>_CLK signal ends after TX/RX:
   a. Write to r30[20-19] (clk_mode). Note: The clk_mode setting can also be changed per transaction.
5. Configure the wire, tst, and rx_en_counter delay values:
   a. PRU_ICSS_PRU0_ED_CHm_CFG0_REG[10-0] PRU0_ED_TX_WDLYm for wire delay (where n = 0 or 1 and m = 0 to 2)

Copyright © 2024 Texas Instruments Incorporated

b. PRU_ICSS_PRU0_ED_CHm_CFG1_REG[15-0] PRU0_ED_TST_DELAY_COUNTERm for tst delay (where n = 0 or 1 and m = 0 to 2)
c. PRU_ICSS_PRU0_ED_CHm_CFG1_REG[31-16] PRU0_ED_RX_EN_COUNTER for auto-delay between TX and RX (where n = 0 or 1 and m = 0 to 2)

7.4.4.2.2.3.6.4.2 TX - Single Shot

Follow these steps to configure the Peripheral I/F channel(s) for a single shot transmission:

1. (Optional) Configure TX FIFO for MSB (default) or LSB:
   a. PRU_ICSS_PRU0_ED_CHm_CFG0_REG[31] PRU0_ED_TX_FIFO_SWAP_BITSm (where n = 0 or 1 and m = 0 to 2)
2. Pre-load TX FIFO:
   a. Select TX channel by writing the desired channel number to R30[17-16] (tx_ch_sel)
   b. Write 1-4 bytes of data to r30[7-0] (tx_data). At each r30[7-0] write, data will be pushed into the FIFO.
   c. Repeat Steps 2a and 2b for all desired channels.
3. Configure TX frame size if less than 4 full bytes loaded into FIFO:
   a. PRU_ICSS_PRU0_ED_CHm_CFG0_REG[15-11] PRU0_ED_TX_FRAME_SIZEm (where n = 0 or 1 and m = 0 to 2)
4. Push TX FIFO data to PERIF<m>_OUT (see Section 4.4.2.2.3.6.3.2 for the PERIF<m>_CLK and PERIF<m>_OUT start time relationship);
   a. To start TX on all channels, set r31[20] = 1 (tx_global_go).
   b. To start TX on individual channel:
      i. Select TX channel by writing the desired channel number to R30[17-16] (tx_ch_sel)
      ii. Set R31[18] = 1 (tx_channel_go)
5. If PRU_ICSS_PRU0_ED_CHm_CFG1_REG[31-16] PRU0_ED_RX_EN_COUNTERm > 0 (where n = 0 or 1 and m = 0 to 2), then the channel will automatically switch into RX mode. See Section 4.4.2.2.3.6.4.4 for an example of how to program and configure RX content.
6. If PRU_ICSS_PRU0_ED_CHm_CFG1_REG[31-16] PRU0_ED_RX_EN_COUNTERm = 0, poll either r31[21, 13, or 5] (tx_global_reinit_active/busy[2,1,0]) or PRU_ICSS_PRU0_ED_TX_CFG_REG[7, 6, or 5] PRU0_ED_BUSY_m (where m = 0 to 2, indicates channel number) for when TX is complete

Note

The PERIF<m>_CLK Peripheral I/F requires that PERIF<m>_CLK be in a high state at the beginning of a new transaction. If the clock ended the single shot transmission in low state, then the clock needs to be reset before sending more data. The steps to reset PERIF<m>_CLK are:

1. Set R31[19] = 1 (tx_global_reinit) to reset clock high
2. Wait until PRU0_ED_BUSY_m bit is cleared
3. Re-configure R30[20-19] (clk_mode), since reinit will reset the clk_mode to "Free-running/stop-high" mode

7.4.4.2.2.3.6.4.3 TX - Continuous FIFO Loading

Follow these steps to configure the Peripheral I/F channel(s) for a continuous loading transmission:

1. (Optional) Configure TX FIFO for MSB (default) or LSB:
   a. PRU_ICSS_PRU0_ED_CHm_CFG0_REG[31] PRU0_ED_TX_FIFO_SWAP_BITSm
2. Pre-load TX FIFO:
   a. Select TX channel by writing the desired channel number to r30[17-16] (tx_ch_sel)
   b. Write 1-4 bytes of data to r30[7-0] (tx_data). At each r30[7-0] write, data will be pushed into the FIFO.
   c. Repeat Steps 2a and 2b for all desired channels.
3. Configure TX frame size to continuously transmit the TX FIFO until empty:
   a. Set PRU_ICSS_PRU0_ED_CHm_CFG0_REG[15-11] PRU0_ED_TX_FRAME_SIZEm = 0h
4. Push TX FIFO data to PERIF<m>_OUT (see Section 4.4.2.2.3.6.3.2 for the PERIF<m>_CLK and PERIF<m>_OUT start time relationship):

Copyright © 2024 Texas Instruments Incorporated

a. To start TX on all channels, set r31[20] = 1 (tx_global_go).
b. To start TX on individual channel:
   i. Select TX channel by writing the desired channel number to r30[17-16] (tx_ch_sel)
   ii. Set r31[18] = 1 (tx_channel_go)

5. Monitor line rate and reload FIFO:
   a. Polling r31[xx, 12-10, 4-2] (tx_fifo_sts<m>)
   b. When FIFO level is at 2 bytes, load next 2 bytes of data (see Step 2). Do not let the FIFO get close to 0. Once the FIFO runs empty, the hardware will assume the PRU has reached end of the last transmit. Any new writes to the FIFO will NOT be sent until the software sends another tx_channel_go bit. Note: There are also underrun and overrun error flags that can be monitored.
6. To end TX operation, do not send any new data to FIFO.
   a. If PRU_ICSS_PRU0_ED_CHm_CFG1_REG[31-16] PRU0_ED_RX_EN_COUNTERm > 0 (where n = 0 or 1 and m = 0 to 2), then the channel will automatically switch into RX mode. See Section 4.4.2.2.3.6.4.4 for an example of how to program and configure RX content.
   b. If PRU_ICSS_PRU0_ED_CHm_CFG1_REG[31-16] PRU0_ED_RX_EN_COUNTERm = 0, poll either r31[21, 13, or 5] (tx_global_reinit_active/busy[2,1,0]) or PRU_ICSS_PRU0_ED_TX_CFG_REG[7, 6, or 5] PRU0_ED_BUSY_m (where m = 0 to 2, indicates channel number) for when TX is complete

Note

The PERIF<m>_CLK Peripheral I/F requires that PERIF<m>_CLK be in a high state at the beginning of a new transaction. If the clock ended the continuous loading transmission in low state, then the clock needs to be reset before sending more data. The steps to reset PERIF<m>_CLK are:

1. Set R31[19] = 1 (tx_global_reinit) to reset clock high
2. Wait until PRU0_ED_BUSY_m is cleared
3. Re-configure R30[20-19] (clk_mode), since reinit will reset the clk_mode to "Free-running/stop-high" mode

7.4.4.2.2.3.6.4.4 RX - Auto Arm or Non-Auto Arm

Follow these steps to configure the Peripheral I/F channel(s) to receive data:

1. Configure RX and frame size:
   a. PRU_ICSS_PRU0_ED_CHm_CFG0_REG[27-16] PRU0_ED_RX_FRAME_SIZEm (where n = 0 or 1 and m = 0 to 2)
2. Configure start bit polarity:
   a. PRU_ICSS_PRU0_ED_RX_CFG_REG[3] RX_SB_POL (PRU0 or PRU1)
   b. For the non-auto arm use case, set r30[26, 25, 24] = 1 (rx_en<m>)
   c. For the auto arm use case, rx_en<m> will be automatically enabled at the end of a TX operation when PRU_ICSS_PRU0_ED_CHm_CFG1_REG[31-16] PRU0_ED_RX_EN_COUNTERm > 0 (where n = 0 or 1 and m = 0 to 2)
3. RX FIFO will start filling on the first start bit (PERIF<m>_IN = 1). The data will be captured on the positive edge of the PERIF<m>_CLK and shifted into the LSB position of the 8-bit shadow register.
4. Poll for r31[26, 25, 24] (val<m>) assertion. The valid flag will be asserted when n bits of data (determined by PRU_ICSS_PRU0_ED_RX_CFG_REG[2-0] PRU0_ED_RX_SAMPLE_SIZE) have been collected.
5. Fetch data by reading r31[23-16, 15-8, 7-0] (rx_data_out<m>). The data will remain constant for one data frame, and PRU must read data and clear valid flag within this time. Otherwise, an overflow will occur – r31[29, 28, 27] (ovf<m>) = 1 - indicating that val<m> has been continuously asserted for longer than one data frame.
6. The clock will be stopped based on the r30[20-19] (clk_mode) configured before the start of the RX operation.
7. Clear r30[26, 25, 24] (rx_en<m>) to disable RX mode. All counters and flags will be reset.

7.4.4.3 PRUSS RAM Index Allocation

The PRUSS module includes integrated ECC Aggregator module to test ECC functionality.

Copyright © 2024 Texas Instruments Incorporated

Table 7-56 shows the mapping of the RAM IDs to the ECC RAMs serviced by the ECC Aggregator.

Table 7-56. Mapping of the RAM IDs to the ECC RAMs

RAM Index	ECC RAM Prefix	Description
0	pr<k>_dram0	Data RAM0 (8KB)
1	pr<k>_dram1	Data RAM1 (8KB)
2	pr<k>_pru0_iram	PRU0 Instruction Memory (16KB)
3	pr<k>_pru1_iram	PRU1 Instruction Memory (16KB)
4	pr<k>_ram	Shared Data RAM2 (32KB)

Copyright © 2024 Texas Instruments Incorporated

7.4.5 PRUSS Broadside Accelerators

7.4.5.1 PRUSS Broadside Accelerators Overview

The PRUSS supports a broadside interface, which uses the XFR (XIN, XOUT, or XCHG) instruction to transfer the contents of PRUn (where n = 0 or 1) registers to or from accelerators. This interface enables up to 31 registers (R0-R30, or 124 bytes) to be transferred in a single instruction. This section details the various accelerators that are available to the PRUn through the broadside interface.

Each of those functions have a unique XIN ID to determine which operation will occur. For more information see Table 7-32.

7.4.5.2 PRUSS Data Processing Accelerators Functional

7.4.5.2.1 PRU Multiplier with Accumulation (MPY/MAC)

This section describes the MAC (multiplier with accumulation) module integrated to PRU0/PRU1 cores.

Each of the two PRU cores (PRU0/PRU1) has a designated unsigned multiplier with accumulation (MPY/MAC). The MAC supports two modes of operation: Multiply Only and Multiply and Accumulate.

The MAC is directly connected with the PRU internal registers R25-R29 and uses the broadside load/store PRU interface and XFR instructions to both control and mode of the MAC and import the multiplication results into the PRU.

The PRU MPY/MAC features are:

- Configurable Multiply Only and Multiply and Accumulate functionality via PRU register R25
- 32-bit operands with direct connection to PRU registers R28 and R29
- 64-bit result (with carry flag) with direct connection to PRU registers R26 and R27
- One clock cycle per operation
- PRU broadside interface and XFR instructions (XIN, XOUT) allow for importing multiplication results and initiating accumulate function

7.4.5.2.1.1 PRU MAC Operations

7.4.5.2.1.1.1 PRU versus MAC Interface

The MAC directly connects with the PRU internal registers R25-R29 through use of the PRU broadside interface and XFR instructions. Figure 7-37 shows the functionality of each register.

Copyright © 2024 Texas Instruments Incorporated

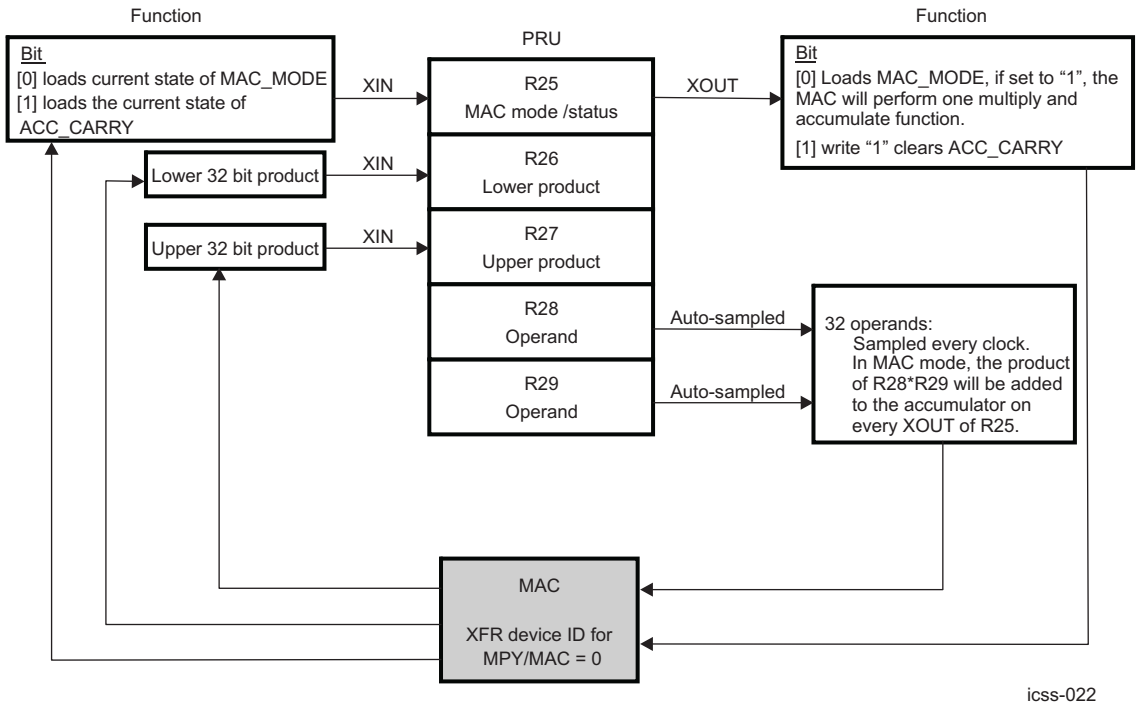

Figure 7-37. Integration of the PRU and MPY/MAC

The XFR instructions (XIN and XOUT) are used to load/store register contents between the PRU core and the MAC. These instructions define the start, size, direction of the operation, and device ID. The device ID number corresponding to the MPY/MAC is shown in Table 7-57.

Table 7-57. MPY/MAC XFR ID

Device ID	Function
0	Selects MPY/MAC

The PRU register R25 is mapped to the MAC_CTRL_STATUS register (Table 7-58). The MAC's current status (MAC_MODE and ACC_CARRY states) is loaded into R25 using the XIN command on R25. The PRU sets the MAC's mode and clears the ACC_CARRY using the XOUT command on R25.

Table 7-58. MAC_CTRL_STATUS Register (R25) Field Descriptions

Bit	Field	Description
7-2	RESERVED	Reserved
1	ACC_CARRY	Write 1 to clear. It is sticky. It is set 0 cycles after the event. 0h: 64-bit accumulator carry has not occurred 1h: 64-bit accumulator carry occurred
0	MAC_MODE	0h: Accumulation mode disabled and accumulator is cleared 1h: Accumulation mode enabled

The two 32-bit operands for the multiplication are loaded into R28 and R29. These registers have a direction connection with the MAC. Therefore, XOUT is not required to load the MAC. In multiply mode, the MAC samples these registers every clock cycle. In multiply and accumulate mode, the MAC samples these registers every XOUT R25[7-0] transaction when MAC_MODE = 1.

The product from the MAC is linked to R26 (lower 32 bits) and R27 (upper 32 bits). The product is loaded into register R26 and R27 using XIN.

Copyright © 2024 Texas Instruments Incorporated

7.4.5.2.1.1.2 Multiply only mode(default state), MAC_MODE = 0

The Figure 7-38 summarizes the MAC operation in "Multiply-only"mode, in which the MAC multiplies the contents of R28 and R29 on every clock cycle.

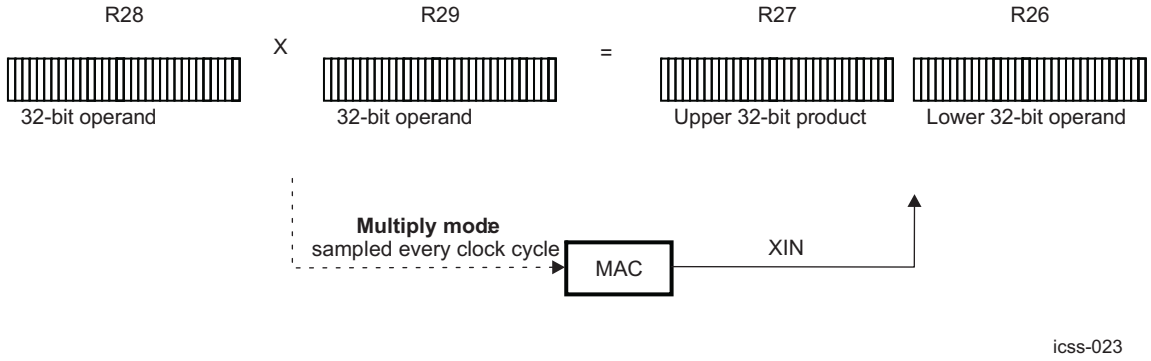

Figure 7-38. MAC Multiply-only Mode- Functional Diagram

7.4.5.2.1.1.2.1 Programming PRU MAC in "Multiply-ONLY" mode

The following steps are performed by the PRU firmware for multiply-only mode:

1. 1. Enable multiply only MAC_MODE.
    a. (a) Clear R25[0] for multiply only mode.
    b. (b) Store MAC_MODE to MAC using XOUT instruction with the following parameters:
        - Device ID = 0
        - Base register = R25
        - Size = 1
2. 2. Load operands into R28 and R29.
3. 3. Delay at least 1 PRU cycle before executing XIN in step 4.
4. 4. Load product into PRU using XIN instruction on R26, R27.

Repeat steps 2 and 4 for each new operand.

7.4.5.2.1.1.3 Multiply and Accumulate Mode, MAC_MODE = 1

The Figure 7-39 summarizes the MAC operation in "Multiply and Accumulate" mode. On every XOUT R25_REG[7-0] transaction, the MAC multiplies the contents of R28 and R29, adds the product to its accumulated result, and sets ACC_CARRY if an accumulation overflow occurs.

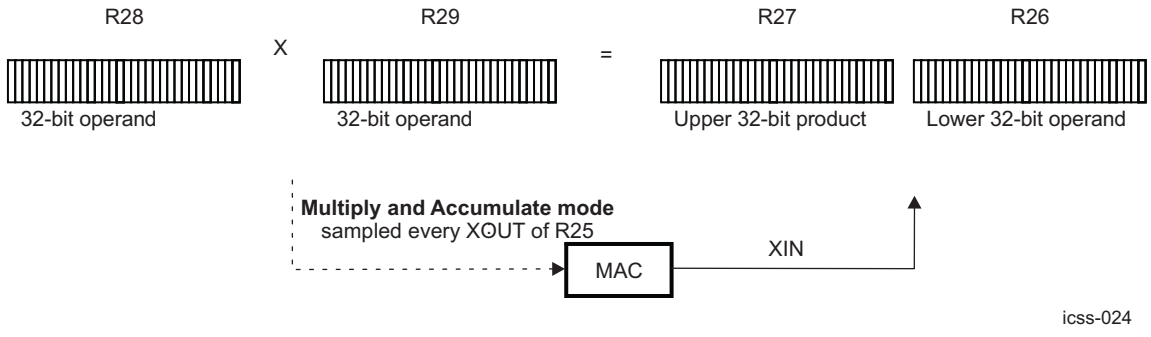

Figure 7-39. MAC Multiply and Accumulate Mode Functional Diagram

7.4.5.2.1.1.3.1 Programming PRU MAC in Multiply and Accumulate Mode

The following steps are performed by the PRU firmware for multiply and accumulate mode:

1. Enable multiply and accumulate MAC_MODE.

Copyright © 2024 Texas Instruments Incorporated

(a) Set R25[1-0] = 1 for accumulate mode.

(b) Store MAC_MODE to MAC using XOUT instruction with the following parameters:

- Device ID = 0
- Base register = R25
- Size = 1

2. Clear accumulator and carry flag.

(a) Set R25[1-0] = 3 to clear accumulator (R25[1]=1) and preserve accumulate mode (R25[0]=1).

(b) Store accumulator to MAC using XOUT instruction on R25.

3. Load operands into R28 and R29.

4. Multiply and accumulate, XOUT R25[1-0] = 1

Repeat step 4 for each multiply and accumulate using same operands.

Repeat step 3 and 4 for each multiply and accumulate for new operands.

5. Load the accumulated product into R26, R27, and the ACC_CARRY status into R25 using the XIN instruction.

Note

Steps one and two are required to set the accumulator mode and clear the accumulator and carry flag.

7.4.5.2.2 PRU CRC16/32 Module

Each of the PRU0/PRU1 cores have a designated CRC16/32 module.

In general, CRC adds error detection capability to communication systems. The CRC encoder appends redundant bits (or CRC bits) to the systematic data message. During reception of the data message, the received data is also encoded with the same CRC encoder. The 2 sets of CRC bits are compared together. If they match, there were no transmission errors; and if they don't match, a transmission error has been detected.

CRC16/32 supports the following features:

- Supports CRC32:
  - $x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^{8}+x^{7}+x^{5}+x^{4}+x^{2}+x+1$
- Supports CRC16:
  - $x^{16}+x^{15}+x^{2}+1$
- Supports CRC16 - CCITT:
  - $x^{16}+x^{12}+x^{5}+1$
- PRU broadside interface and XFR instructions (XIN, XOUT) allow for importing CRC results and executing accumulate function

7.4.5.2.2.1 PRU and CRC16/32 Interface

The CRC16/32 module directly connects with the PRU internal registers R25-R29 through use of the PRU broadside interface and XFR instructions. Table 7-59 shows the functionality of each register.

The XFR instructions (XIN/XOUT/XCHG) are used to load/store register contents between the PRU core and the CRC16/32 module. These instructions define the start, size, direction of the operation, and device ID. The XFR device ID number corresponding to the CRC16/32 module is 1.

Table 7-59. CRC Register to PRU Port Mapping

CRC Register	R/W	Description	PRU Mapping
CRC_CFG	W	Always write all 4 bytes. bit [0] CRC32_ENABLE: 0: CRC16 mode is selected. Hardware will auto-set init state of CRC_SEED to 0000_0000h. However, for CRC16-CCITT software will need to write the init state of FFFF_FFFFh to CRC_SEED. Note: The CRC16 result value is only 16-bits. 1: CRC32 mode is selected. Hardware will auto-set init state of CRC_SEED will be FFFF_FFFFh. bit [1] CRC_32B_NOT_EMPTY: 0: CRC 32Byte buffer is empty 1: CRC 32Byte buffer is not empty bit [2] CRC16_MOD_ENABLE: 0: CRC16 ($x^{16}+x^{15}+x^{2}+1$) 1: CRC16-CCITT ($x^{16}+x^{12}+x^{5}+1$) - Note: CRC32_ENABLE field must = 0.	R25
CRC_DATA_8_BFLIP	R	8-bit flip of CRC_DATA. CRC_DATA_8_BFLIP has the same byte order as CRC_DATA[31-0], but each byte has all bits flipped. CRC_DATA_32_FLIP[7-0] = CRC_DATA[0-7] CRC_DATA_32_FLIP[15-8] = CRC_DATA[8-15] CRC_DATA_32_FLIP[23-16] = CRC_DATA[16-23] CRC_DATA_32_FLIP[31-24] = CRC_DATA[24-31] For CRC16, only CRC_DATA_8_BFLIP[15-0] are valid. No auto reset on CRC_DATA_8_BFLIP read.	R27
CRC_SEED	W	CRC SEED value. Hardware will auto-initialize the CRC_SEED value to 0000_0000h for CRC16 and FFFF_FFFFh for CRC32. Software only needs to initialize CRC_SEED if a different default value is required. For CRC16-CCITT, software needs to update initial CRC_SEED value to FFFF_FFFFh. Always write 4 bytes. Note: Reading the CRC_DATA register will reset the CRC value to the CRC_SEED state.	R28

Copyright © 2024 Texas Instruments Incorporated

Table 7-59. CRC Register to PRU Port Mapping (continued)

CRC Register	R/W	Description	PRU Mapping
CRC_DATA_32_BFLIP	R	Full 32-bit flip of CRC_DATA CRC_DATA_32_BFLIP[0] = CRC_DATA[31] … CRC_DATA_32_BFLIP[31] = CRC_DATA[0] For CRC16, only CRC_DATA_32_BFLIP[31-16] are valid. No auto reset on CRC_DATA_32_BFLIP read.	R28
CRC_DATA	RW	For Write, must use a fixed width throughout the session. The CRC module supports lower 8-bit, or lower 16-bit, or full 32-bit data widths. For Read, LSB or CRC_DATA[0] is first bit on the wire. For Read, reset the CRC_DATA back to CRC_SEED state. Note: Firmware must add 1 to 2 NOPs after the last XOUT to the XIN. For CRC16, only CRC_DATA[15-0] is valid.	R29

7.4.5.2.2.2 CRC Programming Model

The following steps are performed by the PRU firmware to use the CRC module:

Step1: Configuration (optional)

1. Configure CRC type:
   For CRC32 operation, set CRC32_ENABLE using XOUT instruction with the following parameters:
   - Device ID = 1
   - Base register = R25
   - Size = 1
2. Update CRC_SEED, if required using XOUT with the following parameters:
   - Device ID = 1
   - Base register = R28
   - Size = 1 to 4

Step 2:

1. Load new CRC data into R29
2. Push CRC data to the CRC16/32 module using XOUT with the following parameters:
   - Device ID = 1
   - Base register = R29
   - Size = 1 to 4
3. 1 or 2 NOPS
4. Load the accumulated CRC result into the PRU using the XIN instruction with the following parameters:
   - Device ID = 1
   - Base register = R29
   - Size = 4

Repeat Step 2, numbers 1 and 2 for each new CRC data.

Note

When a session starts, the PRU firmware must use the same write data width throughout the session.

7.4.5.2.2.3 PRU and CRC16/32 Interface (R9:R2)

The PRUSS system implements a new wide 32-Bytes data path. The firmware can perform one XOUT of 32-Bytes, the hardware will feed the CRC16/32 4-Bytes at a time. This will take 20 clock cycles for CRC16 and 12 clock cycles for CRC32 for a 32-Bytes XOUT.

Table 7-60. PRU Register to XFR Mapping

PRU Register	XFR ID	Domain/Function	Description
R9:R2 Data	1	Data	XOUT Only 1-Byte to 32-Bytes in size

7.4.5.2.3 PRUSS Scratch Pad Memory

The PRUSS supports a scratch pad with up to four independent banks accessible by the PRU cores. The PRU cores interact with the scratch pad through broadside load/store PRU interface and XFR instructions. The scratch pad can be used as a temporary place holder for the register contents of the PRU.

7.4.5.2.3.1 PRU0/1 Scratch Pad Overview

The PRUSS scratch pad supports the following features:

- PRU0 and PRU1 cores have three Scratch Pad banks of 30, 32-bit registers (R29 to R0)
- Flexible load/store options:
  - Load/store one byte of R<n> or load/store (R29 to R0) to Bank0, Bank1, Bank2 or Bank3
  - User-defined start byte and length of the transfer
  - Length of transfer ranges from one byte of a register to the entire register content (R29 to R0)
  - Simultaneous transaction supported between PRU0 <-> Bank<n> and PRU1 <-> Bank<m>
- XFR (XIN/XOUT/XCHG) instructions operate in one clock cycle
- Optional XIN/XOUT shift functionality allows remapping of registers (R<n> -> R<m>) during load store operation

Figure 7-40 shows a simplified model of the Scratch Pad and PRU cores integration.

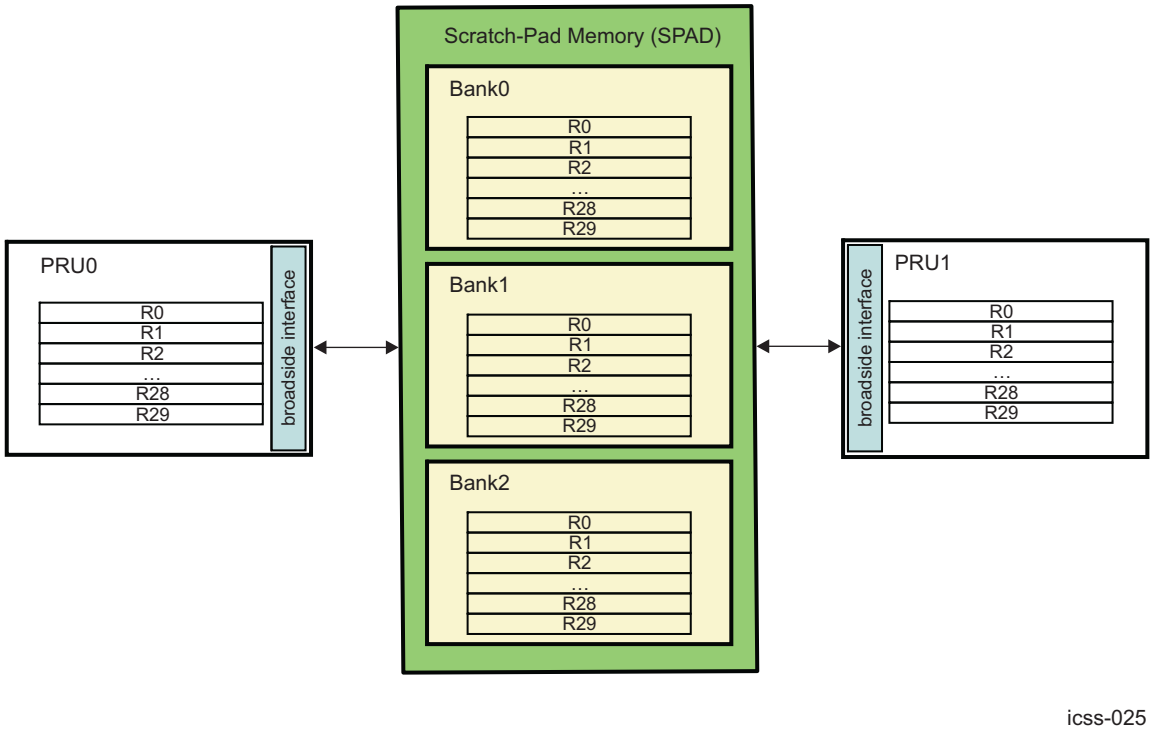

Figure 7-40. Scratch Pad and PRU Integration

7.4.5.2.3.2 PRU0 /1 Scratch Pad Operations

XFR instructions are used to load/store register contents between the PRU cores and the scratch pad banks. These instructions define the start, size, direction of the operation, and device ID. The device ID corresponds to the external source or destination (either a scratch pad bank or the other PRU core). The device ID numbers are shown in Table 7-61.

Table 7-61. Scratch Pad XFR ID

Device ID	Function/Operation
10	Selects Bank0
11	Selects Bank1

Copyright © 2024 Texas Instruments Incorporated

Table 7-61. Scratch Pad XFR ID (continued)

Device ID	Function/Operation
12	Selects Bank2

A collision occurs when two XOUT commands simultaneously access the same asset or device ID. Table 7-62 shows the priority assigned to each operation when a collision occurs.

Table 7-62. Scratch Pad XFR Collision and Stall Conditions

Operation	Collision and Stall Handling
PRU<n> XOUT (->) bank[j]	If both PRU cores access the same bank simultaneously, PRU0 is given priority. PRU1 will temporarily stall until the PRU0 operation completes.

7.4.5.2.3.2.1 Optional XIN/XOUT Shift

The optional XIN/XOUT shift functionality allows register contents to be remapped or shifted within the destination's register space. For example, the contents of PRU0 R6-R8 could be remapped to Bank1 R10-12.

The shift feature is enabled or disabled through the PRU subsystem level register PRU_ICSS_SPP_REG[1] XFR_SHIFT_EN bit. When enabled, R0[4-0] (internal to the PRU) defines the number of 32-bit registers in which content is shifted in the scratch pad bank. Note that scratch pad banks do not have registers R30 or R31.

7.4.5.2.3.2.2 Scratch Pad Operations Examples

The following PRU firmware examples demonstrate the shift functionality. Note: These assume the XFR_SHIFT_EN bit of the PRU_ICSS_SPP_REG register of the PRUSS CFG register space has been set.

XOUT Shift By 4 Registers

Store R4:R7 to R8:R11 in Bank0:

- Load 4 into R0.b0
- XOUT using the following parameters:
  - Device ID = 10
  - Base register = R4
  - Size = 16

XOUT Shift By 9 Registers, With Wrap Around

Store R25:R29 to R4:R9 in Bank1:

- Load 9 into R0.b0
- XOUT using the following parameters:
  - Device ID = 11
  - Base register = R25
  - Size = 20

XIN Shift By 10 Registers

Load R14:R16 from Bank2 to R4:R6:

- Load 10 into R0.b0
- XIN using the following parameters:
  - Device ID = 12
  - Base register = R4
  - Size = 12

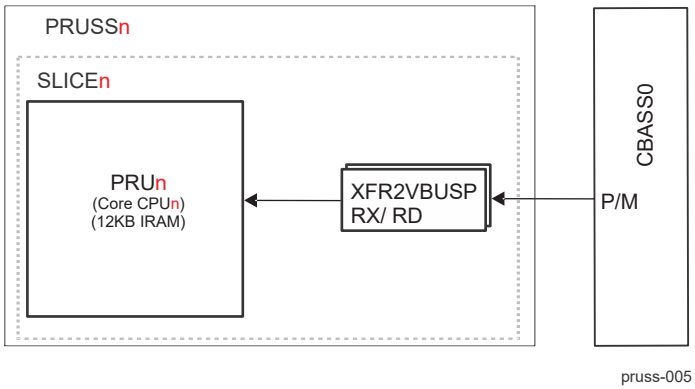
7.4.5.3 PRUSS Data Movement Accelerators Functional

7.4.5.3.1 PRUSS XFR2VBUS Hardware Accelerator

The PRU core can write and read data packets to and from port queues, located in the MSMC SRAM into PRU core registers via XFR2VBUS hardware accelerator. Each of the PRUSS Slices has implemented two RX XFR2VBUS hardware accelerators.



1. n reprsents a valid instance of PRU in a domain.

Figure 7-41. XFR2VBUS Hardware Accelerator

Supported features:

- 2 x XFR2VBUS RX threads

XFR2VBUS RX buffer features:

- 1 x 64 Byte deep RX/Read buffer
  - 4 Byte, 32 Byte, or 64 Byte read size per RD (read) command
  - Optional automatic read command with incrementing address on pop of read data
  - 32 Byte optimization mode available

The ownership of commands and data is flexible. The XFR2VBUS accelerator is shared between PRU cores. Status is available to both cores.

Note: The ownership should be preplanned and static per use model.

The XFR2VBUS is a simple hardware accelerator wich is used to get the lowest read round trip latency from MSMC and to decouple the latency seen by the PRU. Each XFR2VBUS instance is connected to the CBASS0.

The PRUSS system has a total of 2 XFR2VBUS RX hardware accelerators.

7.4.5.3.1.1 Blocking Conditions

The only blocking condition is caused when the VBUSM command/data FIFO is full. It is required that the external bandwidth is very high. All egress commands and data should get sent without head of line blocking. Based on arbitration some delay is possible.

7.4.5.3.1.2 Read Operation with Auto Disabled

The XFR2VBUS supports 1 command in its command FIFO, 1 XOUT to define the address and size (4 Byte, 32 Byte, 64 Byte, aligned). This will cause the VBUSP read command to be issued. Only 1 read command can be in flight. The read address defines the offset of the 64 Byte of read data. The read size defines the size of the transfer, 4 Byte, 32 Byte, 64 Byte, aligned Offset + size must be aligned to 32 Byte width of the bus. 1 XIN, the software can see the status of command FIFO and read data FIFO.

Note: XIN of the read data will fully pop the data, independent of XIN size.

Copyright © 2024 Texas Instruments Incorporated

7.4.5.3.1.3 Read Operation with Auto Enabled

The same features as Auto Disabled are valid with the following exceptions:

64 Byte mode:

- Address needs to be MOD 0x40/64 Byte aligned
- Size needs to be 64 Byte
- 1 XOUT to define the start address, which needs to be MOD 0x40/64 Byte aligned
- The XFR2VBUS will issue 1 new command every time this is 64 Bytes available in the read data FIFO
- 1 XIN of read data will cause a new command to be issued since, 64 Bytes are available
- To stop the issuing new read commands, disable auto mode

32 Byte mode:

- Size needs to be 32 Byte
- 1 XOUT to define the start address, which needs to be MOD 0x20/32 Byte aligned
- The XFR2VBUS will issue 1 new command every time this is 32 Bytes available in the read data FIFO
- 1 XIN of read data will cause a new command to be issued since, 32 Bytes are available
- To stop the issuing of new read command, disable auto mode

Note: XIN of the read data will fully pop the data, independent of XIN size.

7.4.5.3.1.4 Write Operation with Auto Disabled

The XFR2VBUS supports 1 command in the command FIFO.

- 1 XOUT to define the address, data and size (on the fly). 1 Byte, 4 Byte, 32 Byte, 64 Byte and must be aligned.
- Only 1 write command can be in flight since this is VBUSP
- 1 XIN the software can see the status of write command FIFO and write data FIFO

7.4.5.3.1.5 PRU to XFR2VBUS Interface

RD_ID0 = 0x60

RD_ID1 = 0x61

Table 7-63. Read Commands

PRU Register	BS ID	Access Type	Register	Notes
R17-R2	RD_ID1/0	XIN	RD_DATA	Read Data
R18[0]	RD_ID1/0	XOUT	RD_AUTO	Read Auto Mode If 0 -> 1, must write RD_ADDR If 1 -> 0, must not write RD_ADDR, must drain RD_DATA/RD_CMD If 0 -> 0, must write RD_ADDR When set, every RD_DATA pop will cause a new read command and read address to increment by 0x20 for the next read command if size is set to 32 Bytes 0x40 for the next read command if size is set to 64 Bytes In this case, user must set the address to be ether mod 0x20 or 0x40. 4 Byte mode is not supported.
R18[2-1]	RD_ID1/0	XOUT	RD_SIZE	Read Size 0h: 4 Bytes 1h: Reserved 2h: 32 Bytes 3h: 64 Bytes

Copyright © 2024 Texas Instruments Incorporated

Table 7-63. Read Commands (continued)

PRU Register	BS ID	Access Type	Register	Notes
R18[0]	RD_ID1/0	XIN	RD_BUSY	Read Busy Status 0h: Idle 1h: Active (RD CMD FIFO LEVEL !=0) or (RD DATA FIFO LEVEL !=0)
R18[1]	RD_ID1/0	XIN	RD_CMD_FL	Read command FIFO Level 0h: Empty 1h: Occupied Note: It only pop the read command FIFO after the read data has arrived
R18[2]	RD_ID1/0	XIN	RD_DATA_FL	Read data FIFO Level 0h: Empty 1h: Occupied 32 byte or 64 byte Note: In 64 byte mode, the user must wait for RD_MST_REQ = 0h before reading the FIFO.
R18[3]	RD_ID1/0	XIN	RD_MST_REQ	RD MST RED 0h = Last data has been latched 1h = Last data is still in flight Note: In Auto mode, the user must insure that this bit is 0h and wait an additional NOP before user disables Auto mode to prevent a race condition.
R20:R19	RD_ID1/0	XOUT	RD_ADDR	Read address 48-bits 0x20 for the next read command if size is set to 32 Bytes 0x40 for the next read command if size is set to 64 Bytes The address can be the full 48-bits or just the lower 32-bits of the address, it will use the current state of the upper 16-bits

7.4.5.3.1.6 XFR2VBUS Programming Model

Read:

- Wait RD_BUSY = 0h
- XOUT R18 (configure RD_AUTO/ RD_SIZE); R19 (RD_ADDR)
- Wait WR_BUSY = 0h OR RD_DATA_FL = 1h
- XIN RD_DATA (Repeat if RD_AUTO is enabled and need new RD_DATA, must always check RD_DATA_FL before XIN RD_DATA)

Copyright © 2024 Texas Instruments Incorporated

7.4.6 PRUSS Local INTC

The PRUSS interrupt controller (INTC) maps interrupts coming from different parts of the device (mapped to PRU-ICSS) to a reduced set of PRUSS interrupt channels.

The interrupt controller has the following features:

- Capturing up to 64 System Events (inputs):
- Supports up to 10 output interrupt channels.
- Generation of 10 Host Interrupts
  - 2 Host Interrupts shared between the PRUs (PRU0 and PRU1).
  - 8 Host Interrupts exported from the PRUSS internal INTC for signaling the device level interrupt controllers (pulse and level provided).
- Each event can be enabled and disabled.
- Each host event can be enabled and disabled.
- Hardware prioritization of events.

7.4.6.1 PRUSS Interrupt Controller Functional Description

The PRUSS INTC supports up to 64 interrupts from different peripherals and PRUs. The INTC maps these events to 10 channels inside the INTC (see Figure 7-42). Interrupts from these 10 channels are further mapped to 10 Host Interrupts.

- Any of the 64 internal interrupts can be mapped to any of the 10 channels.
- Multiple interrupts can be mapped to a single channel.
- An interrupt should not be mapped to more than one channel.
- Any of the 10 channels can be mapped to any of the 10 host interrupts. It is recommended to map channel “x” to host interrupt “x”, where x is from 0 to 9.
- A channel should not be mapped to more than one host interrupt
- For channels mapping to the same host interrupt, lower number channels have higher priority.
- For interrupts on same channel, priority is determined by the hardware interrupt number. The lower the interrupt number, the higher the priority.
- Host Interrupt 0 is connected to bit 30 in register 31 (R31) of PRU0 and PRU1 in parallel.
- Host Interrupt 1 is connected to bit 31 in register 31 (R31) for PRU0 and PRU1 in parallel.
- Host Interrupts 2 through 9 exported from PRUSS and mapped to device level interrupt controllers.

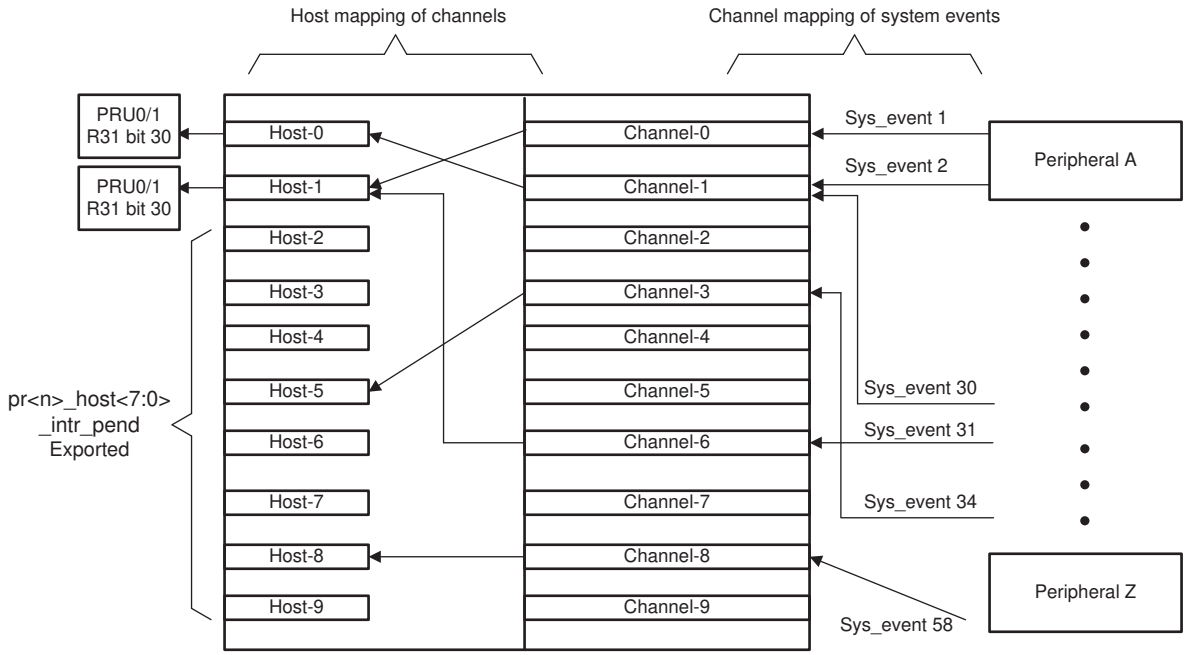


Figure 7-42. PRUSS Interrupt Controller Block Diagram

Copyright © 2024 Texas Instruments Incorporated

7.4.6.1.1 PRUSS Interrupt Controller Events

All PRUSS system events are interrupt inputs. System events 32 through 63 are external and generated from different peripherals. System events 0 through 31 are internal for PRUSS sources.

7.4.6.1.2 PRUSS Interrupt Controller System Events Flow

The ICSS_INTC module controls the event mapping to the host interrupt interface. Events are generated by the device peripherals or PRUs. The INTC receives the internal interrupts and maps them to internal channels. The channels are used to group interrupts together and to prioritize them. These channels are then mapped onto the host interrupts. Interrupts from the system side are active high in polarity.

The INTC encompasses many functions to process the system interrupts and prepare them for the host interface. These functions are: processing, enabling, status, channel mapping, host interrupt mapping, prioritization, and host interfacing. Figure 7-43 illustrates the flow of interrupts through the functions to the host. The following subsections describe each part of the flow.

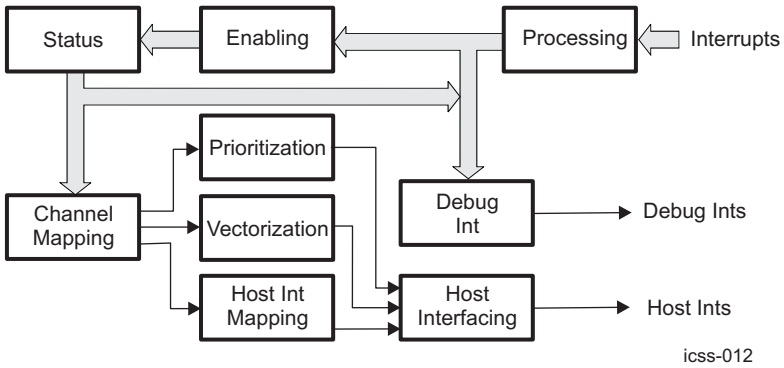

Figure 7-43. Flow of System Interrupts to Host

7.4.6.1.2.1 PRUSS Interrupt Processing

This block does following tasks:

- Synchronization of slower and asynchronous interrupts
- Conversion of polarity to active high
- Conversion of interrupt type to pulse interrupts

After the processing block, all interrupts will be active high pulses.

7.4.6.1.2.1.1 PRUSS Interrupt Enabling

The next stage of INTC is to enable interrupts based on programmed settings. The following sequence has to be followed to enable interrupts:

- Enable required interrupts: System interrupts that are required to get propagated to host are to be enabled individually by writing to [9-0] ENABLE_SET_INDEX bit field in the interrupt enable indexed set register (ICSS_INTC_ENABLE_SET_INDEX_REG). The interrupt to enable is the index value written. This sets the Enable Register bit of the given index.
- Enable required host interrupts: By writing 1h to the appropriate bit of the [9-0] HINT_ENABLE_SET_INDEX bit field in the host interrupt enable indexed set register (ICSS_INTC_HINT_ENABLE_SET_INDEX_REG), enable the required host interrupts. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if that host interrupt is already enabled.
- Enable all host interrupts: By setting the [0] ENABLE_HINT_ANY bit in the global enable register (ICSS_INTC_GLOBAL_ENABLE_HINT_REG) to 1h, all host interrupts will be enabled. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable.

Copyright © 2024 Texas Instruments Incorporated

7.4.6.1.2.2 PRUSS Interrupt Status Checking

The next stage is to capture which interrupts are pending. There are two kinds of pending status: raw status and enabled status. Raw status is the pending status of the interrupt without regards to the enable bit for the interrupt. Enabled status is the pending status of the interrupts with the enable bits active. When the enable bit is inactive, the enabled status will always be inactive. The enabled status of interrupts is captured in interrupt status enabled/clear registers (ICSS_INTC_ENA_STATUS_REG0 to ICSS_INTC_ENA_STATUS_REG4).

Status of interrupt 'N' is indicated by the N-th bit of ICSS_INTC_ENA_STATUS_REG0 to ICSS_INTC_ENA_STATUS_REG4. Since there are 160 interrupts, five 32-bit registers are used to capture the enabled status of interrupts. The pending status reflects whether the interrupt occurred since the last time the status register bit was cleared. Each bit in the status register can be individually cleared.

7.4.6.1.2.3 PRUSS Interrupt Channel Mapping

The INTC has 10 internal channels to which enabled interrupts can be mapped. Channel 0 has highest priority and channel 9 has the lowest priority. Channels are used to group the interrupts into a smaller number of priorities that can be given to a host interface with a very small number of interrupt inputs.

When multiple interrupts are mapped to the same channel their interrupts are ORed together so that when either is active the output is active. The channel map registers (ICSS_INTC_CH_MAP_REGi) define the channel for each interrupt. There is one register per 4 interrupts; therefore, there are 16 channel map registers for a of 64 interrupts. The channel for each interrupt can be set using these registers.

7.4.6.1.2.3.1 PRUSS Host Interrupt Mapping

The hosts can be the local PRU processors (PRU0 and PRU1) as well as device processors located outside PRUSS such as ARM, etc. The 10 channels from the INTC can be mapped to any of the 10 Host interrupts. The Host map registers (ICSS_INTC_HINT_MAP_REG0 to ICSS_INTC_HINT_MAP_REG4) define the channel for each interrupt. There is one register per 4 channels; therefore, there are 3 host map registers for 10 channels. When multiple channels are mapped to the same host interrupt, then prioritization is done to select which interrupt is in the highest-priority channel and which should be sent first to the host.

7.4.6.1.2.3.2 PRUSS Interrupt Prioritization

The next stage of the INTC is prioritization. Since multiple interrupts can feed into a single channel and multiple channels can feed into a single host interrupt, it is necessary to read the status of all interrupts to determine the highest priority interrupt that is pending. The INTC provides hardware to perform this prioritization with a given scheme so that software does not have to do this. There are two levels of prioritizations:

- The first level of prioritization is between the active channels for a host interrupt. Channel 0 has the highest priority and channel 9 has the lowest. So the first level of prioritization picks the lowest numbered active channel.
- The second level of prioritization is between the active interrupts for the prioritized channel. The interrupt in position 0 has the highest priority and interrupt 159 has the lowest priority. So the second level of prioritization picks the lowest position active interrupt.

This is the final prioritized interrupt for the host interrupt and is stored in the global prioritized innterrupt register (ICSS_INTC_GLB_PRI_INTR_REG). The highest priority pending interrupt with respect to each host interrupts can be obtained using the host interrupt prioritized interrupt registers (ICSS_INTC_PRI_HINT_REGj where j = 0 to 19).

7.4.6.1.2.4 PRUSS Interrupt Nesting

The INTC can also perform a nesting function in its prioritization. Nesting is a method of disabling certain interrupts (usually lower-priority interrupts) when an interrupt is taken so that only those desired interrupts can trigger to the host while it is servicing the current interrupt. The typical usage is to nest on the current interrupt and disable all interrupts of the same or lower priority (or channel). Then the host will only be interrupted from a higher priority interrupt.

The nesting is done in one of three methods:

Copyright © 2024 Texas Instruments Incorporated

1. Nesting for all host interrupts, based on channel priority: When an interrupt is taken, the nesting level is set to its channel priority. From then, that channel priority and all lower priority channels will be disabled from generating host interrupts and only higher priority channels are allowed. When the interrupt is completely serviced, the nesting level is returned to its original value. When there is no interrupt being serviced, there are no channels disabled due to nesting. The global nesting level register (ICSS_INTC_GLB_NEST_LEVEL_REG) allows the checking and setting of the global nesting level across all host interrupts. The nesting level is the channel (and all of lower priority channels) that are nested out because of a current interrupt.
2. Nesting for individual host interrupts, based on channel priority: Always nest based on channel priority for each host interrupt individually. When an interrupt is taken on a host interrupt, then, the nesting level is set to its channel priority for just that host interrupt, and other host interrupts do not have their nesting affected. Then for that host interrupt, equal or lower priority channels will not interrupt the host but may on other host interrupts if programmed. When the interrupt is completely serviced the nesting level for the host interrupt is returned to its original value. The host interrupt nesting level registers (ICSS_INTC_NEST_LEVEL_REGj where j = 0 to 19) display and control the nesting level for each host interrupt. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.
3. Software manually performs the nesting of interrupts. When an interrupt is taken, the software will disable all the host interrupts, manually update the enables for any or all the interrupts, and then re-enables all the host interrupts. This now allows only the interrupts that are still enabled to trigger to the host. When the interrupt is completely serviced the software must reverse the changes to re-enable the nested out interrupts. This method requires the most software interaction but gives the most flexibility if simple channel based nesting mechanisms are not adequate.

7.4.6.1.2.5 PRUSS Interrupt Status Clearing

After servicing the interrupt (after execution of the ISR), interrupt status is to be cleared. If a interrupt status is not cleared, then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. It is also essential to clear all interrupts before the PRU is halted as the PRU does not power down unless all the interrupt status are cleared. For clearing the status of an interrupt, whose interrupt number is N, write a 1h to the Nth bit position in the interrupt status enabled/clear registers (ICSS_INTC_ENA_STATUS_REG0 to ICSS_INTC_ENA_STATUS_REG4). Interrupt N can also be cleared by writing the value N into the interrupt status indexed clear register (ICSS_INTC_STATUS_CLR_INDEX_REG).

7.4.6.1.3 PRUSS Interrupt Disabling

At any time, if any interrupt is not to be propagated to the host, then that interrupt should be disabled. For disabling an interrupt whose interrupt number is N, write a 1h to the Nth bit in the interrupt enable clear registers (ICSS_INTC_ENABLE_CLR_REG0 to ICSS_INTC_ENABLE_CLR_REG4). Interrupt N can also be disabled by writing the value N in the interrupt enable clear index register (ICSS_INTC_ENABLE_CLR_INDEX_REG).

7.4.6.2 PRUSS Interrupt Controller Basic Programming Model

Follow these steps to configure the interrupt controller.

1. Set polarity and type of event through the Interrupt Polarity Registers (ICSS_INTC_POLARITY_REG0 to ICSS_INTC_POLARITY_REG4) and the Interrupt Type Registers (ICSS_INTC_POLARITY_REG0 to ICSS_INTC_POLARITY_REG4). Polarity of all interrupts is always high. Type of all interrupts is always pulse (after the processing block).
2. Map event to INTC channel through ICSS_INTC_CH_MAP_REGi (where i=0 to 39) channel mapping registers.
3. Map channel to host interrupt through ICSS_INTC_HINT_MAP_REG0 to ICSS_INTC_HINT_MAP_REG4 registers. Recommended channel “x” to be mapped to host interrupt “x”.
4. Clear interrupt by writing 1h to ICSS_INTC_ENA_STATUS_REG0 to ICSS_INTC_ENA_STATUS_REG4 registers.
5. Enable host interrupt by writing index value to ICSS_INTC_HINT_ENABLE_SET_INDEX_REG register.
6. Enable interrupt nesting if desired.
7. Globally enable all interrupts through register ICSS_INTC_GLOBAL_ENABLE_HINT_REG[0] ENABLE_HINT_ANY bit.

7.4.6.3 PRUSS Interrupt Requests Mapping

The PRU-ICSS Interrupt Controller lines 0 through 31 are mapped to internal events which are generated by PRUSS integrated modules. Lines 32 to 63 are external and generated from different peripherals. Table 7-64 shows mapping of the different PRUSS internally sourced IRQ events to PRUSS INTC interrupt lines 0 through 63.

Table 7-64. PRUSS IP Internal Interrupts

7.4.7 PRUSS UART Module

This section describes an Universal Asynchronous Receive and Transmit (UART) module integrated into the PRUSS subsystem. Hereinafter the module will be referred as PRUSS UART0.

7.4.7.1 PRUSS UART Overview

The PRUSS UART0 peripheral is based on the industry standard TL16C550 asynchronous communications element, which in turn is a functional upgrade of the TL16C450. The information in this chapter assumes that user is familiar with these standards.

Functionally similar to the TL16C450 on power up (single character or TL16C450 mode), the PRUSS UART0 can be placed in an alternate FIFO (TL16C550) mode. This relieves the CPU of excessive software overhead by buffering received and transmitted characters. The receiver and transmitter FIFOs store up to 16 bytes including three additional bits of error status per byte for the receiver FIFO.

The PRUSS UART0 performs serial-to-parallel conversions on data received from a peripheral device and parallel-to-serial conversion on data received from the CPU. The CPU can read the PRUSS UART0 status at any time. The PRUSS UART0 includes control capability and a processor interrupt system that can be tailored to minimize software management of the communications link.

The PRUSS UART0 includes a programmable baud generator capable of dividing the PRUSS UART0 input clock by divisors from 1 to 65535 and producing a 16× reference clock or a 13× reference clock for the internal transmitter and receiver logic.

7.4.7.2 PRUSS UART Environment

This section describes the PRUSS UART0 module interface to the device environment.

7.4.7.2.1 PRUSS UART Pin Multiplexing

Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. For more information on the PRUSS UART0 pin multiplexing, refer to

7.4.7.2.2 PRUSS UART Signal Descriptions

The PRUSS UART0 utilize a minimal number of signal connections to interface with external devices. The PRUSS UART0 signal descriptions are described in Table 7-65.

Table 7-65. PRUSS_UART0 Signal Descriptions

Signal Name	Signal Type	Function
UART0_TXD	Output	Serial data transmit
UART0_RXD	Input	Serial data receive
$\overline{\text{UART0_CTS}}$	Input	Clear-to-Send handshaking signal
$\overline{\text{UART0_RTS}}$	Output	Request-to-Send handshaking signal

7.4.7.2.3 PRUSS UART Protocol Description and Data Format

7.4.7.2.3.1 PRUSS UART Transmission Protocol

The PRUSS UART0 transmitter section includes a transmitter hold register (THR), memory mapped in the register UART_RBR_TBR[17-8] TBR_DATA bitfield and a transmitter shift register (TSR), which is NOT memory mapped. When the PRUSS UART0 is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the PRUSS UART0 line control register UART_LCTR. Based on the settings chosen in this register, the PRUSS UART0 transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

Copyright © 2024 Texas Instruments Incorporated

THR receives data from the internal data bus, and when TSR (transmitter shift register) is ready, the PRUSS UART0 moves the data from THR to TSR. The PRUSS UART0 serializes the data in TSR and transmits the data on the UART0_TXD pin.

In the non-FIFO mode, if THR is empty and the Transmitter Holding Register Empty interrupt (THRE) is enabled in the interrupt enable register (UART_INT_EN[1] ETBEI), an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register UART_INT_FIFO bitfield [3-1] IIR_INTID is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or UART_INT_FIFO[3-1] IIR_INTID bitfield is read.

7.4.7.2.3.2 PRUSS UART Reception Protocol

The PRUSS UART0 receiver section includes a receiver shift register (RSR), that is not memory mapped, and a receiver buffer register (RBR), memory mapped as the register UART_RBR_TBR[7-0] RBR_DATA bitfield. When the PRUSS UART0 is in the FIFO mode, RBR is a 16-byte FIFO. Receiver section control is a function of the PRUSS UART0 line control register - UART_LCTR. Based on the settings chosen in this register, the PRUSS UART0 receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

RSR receives the data bits from the UART0_RXD pin. Then RSR concatenates the data bits and moves the resulting value into RBR (or the receiver FIFO), accessible in the RBR_TBR[7-0] RBR_DATA register bitfield. The PRUSS UART0 also stores three bits of error status information next to each received character, to record a parity error, framing error, or break.

In the non-FIFO mode, when a character is placed in RBR and the receiver data available interrupt is enabled in the interrupt enable register - UART_INT_EN[0] ERBI, an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control MSB part of the register UART_INT_FIFO, and it is cleared when the FIFO contents drop below the trigger level.

7.4.7.2.3.3 PRUSS UART Data Format

The PRUSS UART0 transmits in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + STOP bit (1, 1.5, 2)

It transmits 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1, 1.5, or 2 STOP bits, depending on the STOP bit selection.

The PRUSS UART0 receives in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + 1 STOP bit

It receives 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1 STOP bit.

The protocol formats are shown in Figure 7-44.

Figure 7-44. PRUSS UART Protocol Formats

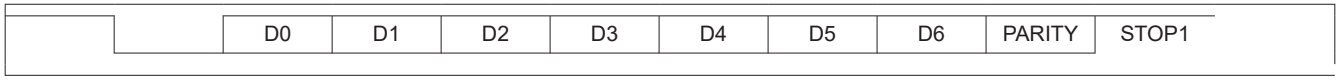
Transmit/Receive for 5-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	PARITY	STOP1

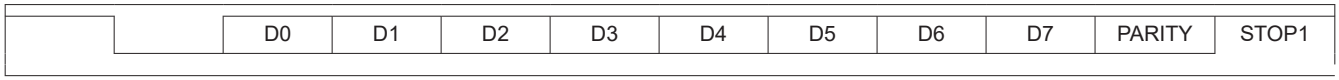
Transmit/Receive for 6-bit data, parity Enable, 1 STOP bit

Copyright © 2024 Texas Instruments Incorporated

Transmit/Receive for 7-bit data, parity Enable, 1 STOP bit



Transmit/Receive for 8-bit data, parity Enable, 1 STOP bit



7.4.7.2.3.3.1 Frame Formatting

Character length is specified using the UART_LCTR[0] WLS0 and UART_LCTR[1] WLS1 bits (see Table 7-67).

The number of stop-bits is specified using the UART_LCTR[2] STB bit (see Table 7-67).

The parity bit is programmed using the UART_LCTR[5] SP, UART_LCTR[4] EPS, and UART_LCTR[3] PEN bits (see Table 7-66).

Table 7-66. Relationship Between SP, EPS, and PEN Bits in LCTR

SP Bit	EPS Bit	PEN Bit	Parity Option
x	x	0	Parity disabled: No PARITY bit is transmitted or checked.
0	0	1	Odd parity selected: Odd number of logic 1s.
0	1	1	Even parity selected: Even number of logic 1s.
1	0	1	Stick parity selected with PARITY bit transmitted and checked as set.
1	1	1	Stick parity selected with PARITY bit transmitted and checked as cleared.

Table 7-67. Number of STOP Bits Generated

STB Bit	WLS Bit	Word Length Selected with WLS Bits	Number of STOP Bits Generated	Baud Clock (BCLK) Cycles
0	x	Any word length	1	16
1	0h	5 bits	1.5	24
1	1h	6 bits	2	32
1	2h	7 bits	2	32
1	3h	8 bits	2	32

7.4.7.2.4 PRUSS UART Clock Generation and Control

The PRUSS UART0 bit clock is derived from an input clock to the PRUSS UART0. See the device-specific Datasheet to check the maximum data rate supported by the PRUSS UART0.

Figure 7-45 is a conceptual clock generation diagram for the PRUSS UART0. The processor clock generator receives a signal from an external clock source and produces a PRUSS UART0 input clock with a programmed frequency. The PRUSS UART0 contains a programmable baud generator that takes an input clock and divides it by a divisor in the range between 1 and (2^{16} - 1) to produce a baud clock (BCLK). The frequency of BCLK is sixteen times (16×) the baud rate (each received or transmitted bit lasts 16 BCLK cycles) or thirteen times (13×) the baud rate (each received or transmitted bit lasts 13 BCLK cycles). When the PRUSS UART0 is receiving, the bit is sampled in the 8th BCLK cycle for 16× over sampling mode and on the 6th BCLK cycle for 13× over-sampling mode. The 16× or 13× reference clock is selected by configuring the mode definition register: UART_MODE[0] OSM_SEL bit. The formula to calculate the divisor is:

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 16} \quad \text{[MODE.OSM_SEL = 0h]}$$

icss-13

Copyright © 2024 Texas Instruments Incorporated

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 13} \quad [\text{MODE.OSM_SEL} = 1\text{h}]$$

icss-14

Two 8-bit register fields:

- UART_DIVMSB[7-0] DLH
- UART_DIVLSB[7-0] DLL,

called divisor latches, hold this 16-bit divisor. DLH holds the most significant bits of the divisor, and DLL holds the least significant bits of the divisor. For information about these register fields, see the PRUSS UART0 register descriptions in the *PRU_UART_UART0 Registers*. These divisor latches must be loaded during initialization of the PRUSS UART0 in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Figure 7-46 summarizes the relationship between the transferred data bit, BCLK, and the PRUSS UART0 input clock. Note that the timing relationship depicted in Figure 7-46 shows that each bit lasts for 16 BCLK cycles. This is in case of 16x over-sampling mode. For 13× over-sampling mode each bit lasts for 13 BCLK cycles.

Example baud rates and divisor values relative to a 150 MHz PRUSS UART0 input clock and 16× over-sampling mode are shown in Table 7-68.

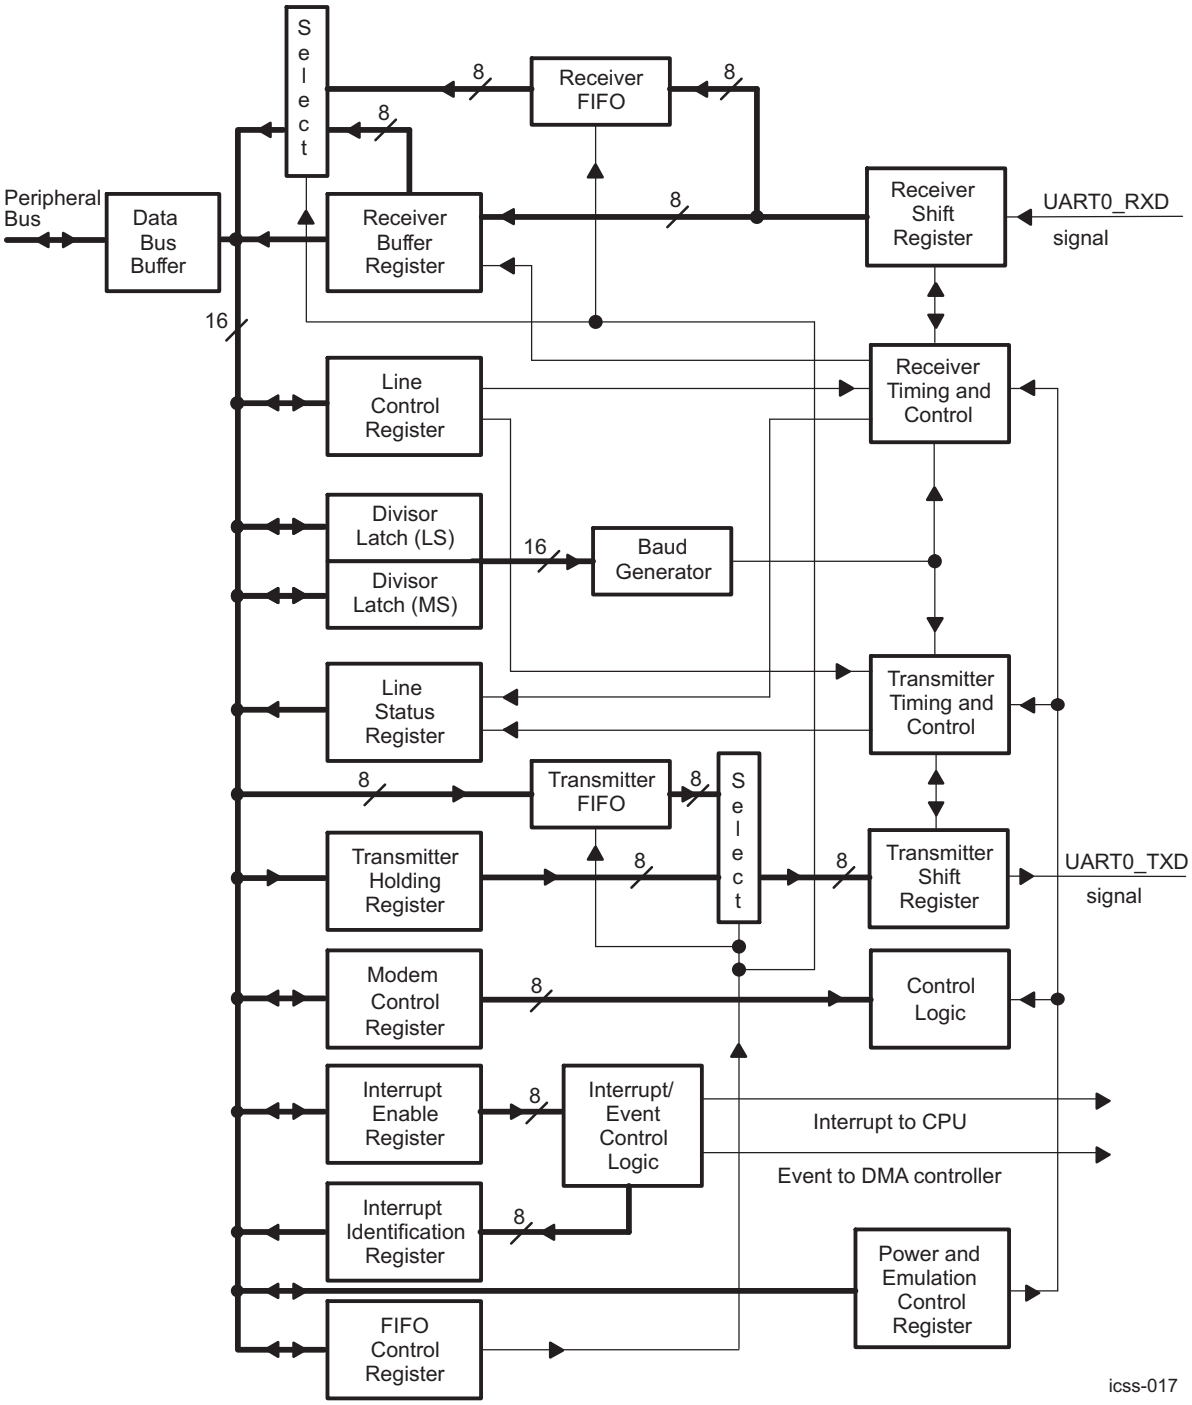
7.4.7.3 PRUSS UART Functional Description

7.4.7.3.1 PRUSS UART Functional Block Diagram

A functional block diagram of the PRUSS UART0 is shown in Figure 7-47.

Copyright © 2024 Texas Instruments Incorporated



NOTE: The value *n* indicates the applicable UART where there are multiple instances. For the PRUSS, there is only one instance and all UART signals should reflect this (e.g., UART0_TXD instead of UARTn_TXD).

Figure 7-47. PRUSS UART Block Diagram

7.4.7.3.2 PRUSS UART Reset Considerations

7.4.7.3.2.1 PRUSS UART Software Reset Considerations

Two bits in the power and emulation management register - UART_PWR, control resetting the parts of the PRUSS UART0:

Copyright © 2024 Texas Instruments Incorporated

- The bit [14]UTRST controls resetting the transmitter only. If bit [14]UTRST = 1h, the transmitter is enabled and active;
  if bit [14]UTRST = 0h, the transmitter is disabled and in reset state.
- The bit [13]URRST controls resetting the receiver only. If [13]URRST = 1h, the receiver is enabled and active;
  if bit [13]URRST = 0h, the receiver is disabled and in reset state.

In each case, putting the receiver and/or transmitter in reset will reset the state machine of the affected portion but will not affect the PRUSS UART0 registers.

7.4.7.3.2.2 PRUSS UART Hardware Reset Considerations

When the processor RESET pin is asserted, the entire processor is reset and is held in the reset state until the RESET pin is released. As part of a device reset, the PRUSS UART0 state machine is reset and the PRUSS UART0 registers are forced to their default states. The default states of the registers are shown in .

7.4.7.3.3 PRUSS UART Power Management

The PRUSS UART0 peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the PRUSS UART0 peripheral and other PRUSS peripherals is controlled by the device . The acts as a power management controller for all of the peripherals on the device. For more details on the power management procedures using the PSC, refer to the *Power Management* section.

7.4.7.3.4 PRUSS UART Interrupt Support

7.4.7.3.4.1 PRUSS UART Interrupt Events and Requests

The PRUSS UART0 generates the interrupt requests described in Table 7-70. All requests are multiplexed through an arbiter to a single PRUSS UART0 interrupt request to the CPU, as shown in Figure 7-48. Each of the interrupt requests has an enable bit in the interrupt enable register (IER) - UART_INT_EN and is recorded in [3-1]IIR_INTID bitfield of UART_INT_FIFO register.

If an interrupt occurs and the corresponding enable bit is set to 1h, the interrupt request is recorded in corresponding UART_INT_FIFO[3-1] IIR_INTID bitfield and is forwarded to the CPU. If an interrupt occurs and the corresponding enable bit is cleared to 0h, the interrupt request is blocked. The interrupt request is neither recorded in UART_INT_FIFO[3-1] IIR_INTID, nor forwarded to the CPU.

7.4.7.3.4.2 PRUSS UART Interrupt Multiplexing

The PRUSS UART0 have dedicated interrupt signals to the CPU and the interrupts are not multiplexed with any other interrupt source.

Table 7-70. PRUSS UART Interrupt Requests Descriptions

PRUSS UART0 Interrupt Request	Interrupt Source	Comment
THREINT	THR-empty condition: The transmitter holding register (THR) or the transmitter FIFO is empty. All of the data has been copied from THR, (i.e. UART_RBR_TBR[7-0] RBR_DATA) to the transmitter shift register (TSR).	If THREINT is enabled in UART_INT_EN register by setting the [1]ETBEI bit, it is recorded in [3-1]IIR_INTID bitfield. As an alternative to using THREINT, the CPU can poll the THRE bit in the line status register UART_LSR1.
RDAINT	Receive data available in non-FIFO mode or trigger level reached in the FIFO mode.	If RDAINT is enabled in UART_INT_EN register, by setting the [0]ERBI bit, it is recorded in INTID bitfield. As an alternative to using RDAINT, the CPU can poll the [0]DR bit in the line status register UART_LSR1. In the FIFO mode, this is not a functionally equivalent alternative because the [0]DR bit does not respond to the FIFO trigger level. The [0]DR bit only indicates the presence or absence of unread characters.

Copyright © 2024 Texas Instruments Incorporated

Table 7-70. PRUSS UART Interrupt Requests Descriptions (continued)

PRUSS UART0 Interrupt Request	Interrupt Source	Comment
RTOINT	Receiver time-out condition (in the FIFO mode only): No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 7-73), and there is at least one character in the receiver FIFO during this time.	The receiver time-out interrupt prevents the PRUSS UART0 from waiting indefinitely, in the case when the receiver FIFO level is below the trigger level and thus does not generate a receiver data-ready interrupt. If RTOINT is enabled in UART_INT_EN register, by setting the [0]ERBI bit, it is recorded in UART_INT_FIFO[3-1] IIR_INTID bitfield. There is no status bit to reflect the occurrence of a time-out condition.
RLSINT	Receiver line status condition: An overrun error, parity error, framing error, or break has occurred.	If RLSINT is enabled in INT_EN register, by setting the [2]ELSI bit, it is recorded in UART_INT_FIFO[3-1] IIR_INTID bitfield. As an alternative to using RLSINT, the CPU can poll the following bits in the line status register UART_LSR1: overrun error indicator (bit [1]OE), parity error indicator (bit [2]PE), framing error indicator ([3]FE), and break indicator ([4]BI).

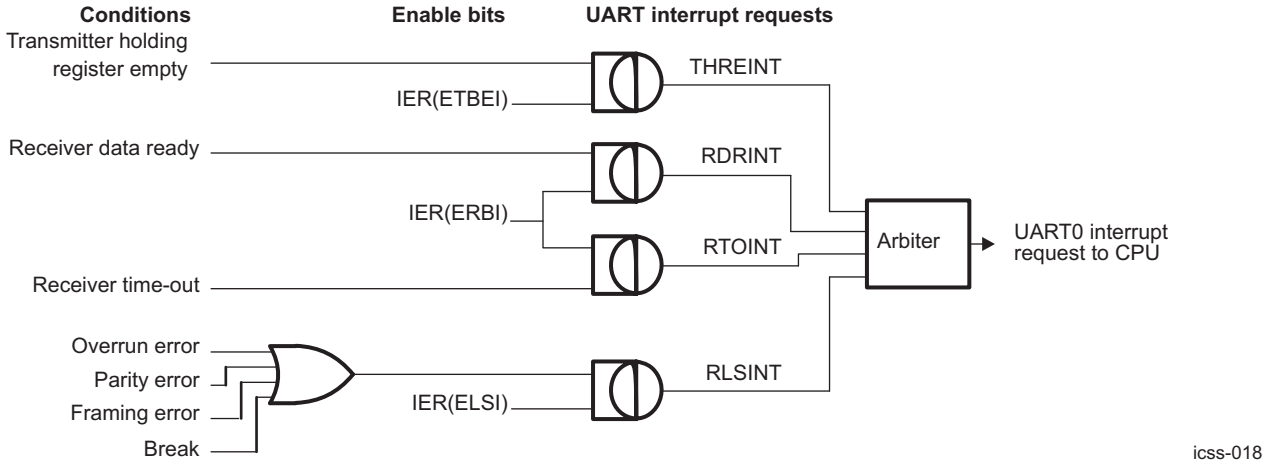


Figure 7-48. PRUSS UART Interrupt Request Enable Paths

Copyright © 2024 Texas Instruments Incorporated

Table 7-71. Interrupt Identification and Interrupt Clearing Information

Priority Level	IIR Bits				Interrupt Type	Interrupt Source	Event That Clears Interrupt
	3	2	1	0			
None	0	0	0	1	None	None	None
1	0	1	1	0	Receiver line status	Overrun error, parity error, framing error, or break is detected.	For an overrun error, reading the line status register UART_LSR1, clears the interrupt. For a parity error, framing error, or break, the interrupt is cleared only after all the erroneous data have been read.
2	0	1	0	0	Receiver data-ready	Non-FIFO mode: Receiver data is ready.	Non-FIFO mode: The receiver buffer register (RBR) is read.
						FIFO mode: Trigger level reached. If four character times pass with no access of the FIFO, the interrupt is asserted again.	FIFO mode: The FIFO drops below the trigger level. (1)
2	1	1	0	0	Receiver time-out	FIFO mode only: No characters have been removed from or input to the receiver FIFO during the last four character times and there is at least one character in the receiver FIFO during this time.	One of the following events: • A character is read from the receiver FIFO (1) • A new character arrives in the receiver FIFO • The [13]URRST bit in the power and emulation management register (UART_PWR) is loaded with 0h.
3	0	0	1	0	Transmitter holding register empty	Non-FIFO mode: Transmitter holding register (THR) is empty.	A character is written to the transmitter holding register (UART_RBR_TBR) or the interrupt identification register (UART_INT_FIFO) is read.
						FIFO mode: Transmitter FIFO is empty.	

(1) In the FIFO mode, the receiver data-ready interrupt or receiver time-out interrupt is cleared by the CPU or by the DMA controller, whichever reads from the receiver FIFO first.

Table 7-72. Interrupt Identification and Interrupt Clearing Information

Priority Level	IIR Bits				Interrupt Type	Interrupt Source	Event That Clears Interrupt
	3	2	1	0			
None	0	0	0	1	None	None	None
1	0	1	1	0	Receiver line status	Overrun error, parity error, framing error, or break is detected.	For an overrun error, reading the line status register UART_LSR1, clears the interrupt. For a parity error, framing error, or break, the interrupt is cleared only after all the erroneous data have been read.
2	0	1	0	0	Receiver data-ready	Non-FIFO mode: Receiver data is ready.	Non-FIFO mode: The receiver buffer register (RBR) is read.
						FIFO mode: Trigger level reached. If four character times pass with no access of the FIFO, the interrupt is asserted again.	FIFO mode: The FIFO drops below the trigger level. (1)
2	1	1	0	0	Receiver time-out	FIFO mode only: No characters have been removed from or input to the receiver FIFO during the last four character times and there is at least one character in the receiver FIFO during this time.	One of the following events: • A character is read from the receiver FIFO (1) • A new character arrives in the receiver FIFO • The [13]URRST bit in the power and emulation management register (UART_PWR) is loaded with 0h.
3	0	0	1	0	Transmitter holding register empty	Non-FIFO mode: Transmitter holding register (THR) is empty.	A character is written to the transmitter holding register (UART_RBR_TBR) or the interrupt identification register (UART_INT_FIFO) is read.
						FIFO mode: Transmitter FIFO is empty.	

(1) In the FIFO mode, the receiver data-ready interrupt or receiver time-out interrupt is cleared by the CPU or by the DMA controller, whichever reads from the receiver FIFO first.

7.4.7.3.6 PRUSS UART DMA Event Support

In the FIFO mode, the PRUSS UART0 generates the following two DMA events:

- **Receive event (URXEVT):** The trigger level for the receiver FIFO (1, 4, 8, or 14 characters) is set with the FIFO control UART_INT_FIFO[7-6] IIR_FIFOEN bitfield. Every time the trigger level is reached or a receiver time-out occurs, the PRUSS UART0 sends a receive event to the UDMA controller. In response, the UDMA controller reads the data from the receiver FIFO by way of the receiver buffer register UART_RBR_TBR[7-0] RBR_DATA. Note that the receive event is not asserted if the data at the top of the receiver FIFO is erroneous even if the trigger level has been reached.
- **Transmit event (UTXEVT):** When the transmitter FIFO is empty (when the last byte in the transmitter FIFO has been copied to the transmitter shift register), the PRUSS UART0 sends an UTXEVT signal to the UDMA controller. In response, the UDMA controller refills the transmitter FIFO by way of the transmitter holding register (THR) - UART_RBR_TBR[7-0] RBR_DATA. The UTXEVT signal is also sent to the UDMA controller when the PRUSS UART0 is taken out of reset using the [14]UTRST bit in the power and emulation management register (UART_PWR).

Activity in DMA channels can be synchronized to these events. In the non-FIFO mode, the PRUSS UART0 generates no DMA events. Any DMA channel synchronized to either of these events must be enabled at the time the PRUSS UART0 event is generated. Otherwise, the DMA channel will miss the event and, unless the PRUSS UART0 generates a new event, no data transfer will occur.

7.4.7.3.7 PRUSS UART Operations

7.4.7.3.7.1 PRUSS UART FIFO Modes

The following two modes can be used for servicing the receiver and transmitter FIFOs:

- FIFO interrupt mode. The FIFO is enabled and the associated interrupts are enabled. Interrupts are sent to the CPU to indicate when specific events occur.
- FIFO poll mode. The FIFO is enabled but the associated interrupts are disabled. The CPU polls status bits to detect specific events.

Because the receiver FIFO and the transmitter FIFO are controlled separately, either one or both can be placed into the interrupt mode or the poll mode.

Copyright © 2024 Texas Instruments Incorporated

7.4.7.3.7.1.1 PRUSS UART FIFO Interrupt Mode

When the receiver FIFO is enabled in the FIFO control register (FCR), mapped in the MSB part of the register UART_INT_FIFO, and the receiver interrupts are enabled in the interrupt enable register UART_INT_EN, the interrupt mode is selected for the receiver FIFO. The following are important points about the receiver interrupts:

- The receiver data-ready interrupt is issued to the CPU when the FIFO has reached the trigger level that is programmed in FCR. It is cleared when the CPU or the DMA controller reads enough characters from the FIFO such that the FIFO drops below its programmed trigger level.
- The receiver line status interrupt is generated in response to an overrun error, a parity error, a framing error, or a break. This interrupt has higher priority than the receiver data-ready interrupt. For details, see Section 7.4.7.3.4.
- The data-ready ([0]DR) bit in the line status register - UART_LSR1, indicates the presence or absence of characters in the receiver FIFO. The [0]DR bit is set when a character is transferred from the receiver shift register (RSR) to the empty receiver FIFO. The [0]DR bit remains set until the FIFO is empty again.
- A receiver time-out interrupt occurs if all of the following conditions exist:
  - At least one character is in the FIFO,
  - The most recent character was received more than four continuous character times ago. A character time is the time allotted for 1 START bit, *n* data bits, 1 PARITY bit, and 1 STOP bit, where *n* depends on the word length selected with the WLS0 and WLS1 bits of the line control register UART_LCTR. See Table 7-73.
  - The most recent read of the FIFO has occurred more than four continuous character times before.
- Character times are calculated by using the baud rate.
- When a receiver time-out interrupt has occurred, it is cleared and the time-out timer is cleared when the CPU or the EDMA controller reads one character from the receiver FIFO. The interrupt is also cleared if a new character is received in the FIFO or if the URRST bit is cleared in the power and emulation management register - PWM.
- If a receiver time-out interrupt has not occurred, the time-out timer is cleared after a new character is received or after the CPU or EDMA reads the receiver FIFO.

When the transmitter FIFO is enabled in UART_INT_FIFO[0] IIR_IPEND bit and the transmitter holding register empty (THRE) interrupt is enabled in UART_INT_EN[1] ETBEI bit, the interrupt mode is selected for the transmitter FIFO. The THRE interrupt occurs when the transmitter FIFO is empty. It is cleared when the transmitter hold register (THR) UART_RBR_TBR[7-0] RBR_DATA bitfield is loaded (1 to 16 characters may be written to the transmitter FIFO while servicing this interrupt) or the [3-1]IIR_INTID bitfield is read in the interrupt identification register UART_INT_FIFO.

Table 7-73. Character Time for Word Lengths

Word Length (*n*)	Character Time	Four Character Times
5	Time for 8 bits	Time for 32 bits
6	Time for 9 bits	Time for 36 bits
7	Time for 10 bits	Time for 40 bits
8	Time for 11 bits	Time for 44 bits

7.4.7.3.7.1.2 PRUSS UART FIFO Poll Mode

When the receiver FIFO is enabled in the FIFO control register (via setting the UART_INT_FIFO[0] IIR_IPEND to 1h) and the receiver interrupts are disabled in the interrupt enable register (UART_INT_EN), the poll mode is selected for the receiver FIFO. Similarly, when the transmitter FIFO is enabled via setting the same bit (UART_INT_FIFO[0] IIR_IPEND to 1h) and the transmitter interrupts are disabled, the transmitted FIFO is in the poll mode. In the poll mode, the CPU detects events by checking bits in the line status register - UART_LSR1:

- The UART_LSR1[7] RXFIFOE bit indicates whether there are any errors in the receiver FIFO.
- The UART_LSR1[6] TEMT bit indicates that both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
- The UART_LSR1[5] THRE bit indicates when THR (mapped in the UART_RBR_TBR[7-0] RBR_DATA bitfield) is empty.

Copyright © 2024 Texas Instruments Incorporated

- The following line status register - UART_LSR1 bits specify which error or errors have occurred:
  - UART_LSR1[4] BI - Break Interrupt
  - UART_LSR1[3] FE – Framing Error
  - UART_LSR1[2] PE – Parity Error
  - UART_LSR1[1] OE – Overrun Error
- The UART_LSR1[0] DR (data-ready) bit is set as long as there is at least one byte in the receiver FIFO.

Also, in the FIFO poll mode:

- The interrupt identification ([3-1] IIR_INTID) bit field in register UART_INT_FIFO are not affected by any events because the interrupts are disabled.
- The PRUSS UART0 does not indicate when the receiver FIFO trigger level is reached or when a receiver time-out occurs.

7.4.7.3.7.2 PRUSS UART Autoflow Control

The PRUSS UART0 can employ autoflow control by connecting the $\overline{\text{UART0_CTS}}$ and $\overline{\text{UART0_RTS}}$ signals. The $\overline{\text{UART0_CTS}}$ input must be active before the transmitter FIFO can transmit data. The $\overline{\text{UART0_RTS}}$ becomes active when the receiver needs more data and notifies the sending device. When $\overline{\text{UART0_RTS}}$ is connected to $\overline{\text{UART0_CTS}}$, data transmission does not occur unless the receiver FIFO has space for the data. Therefore, when two UARTs are connected as shown in Figure 7-49 with autoflow enabled (UART_MCTR[5] AFE = 1h), overrun errors are eliminated.

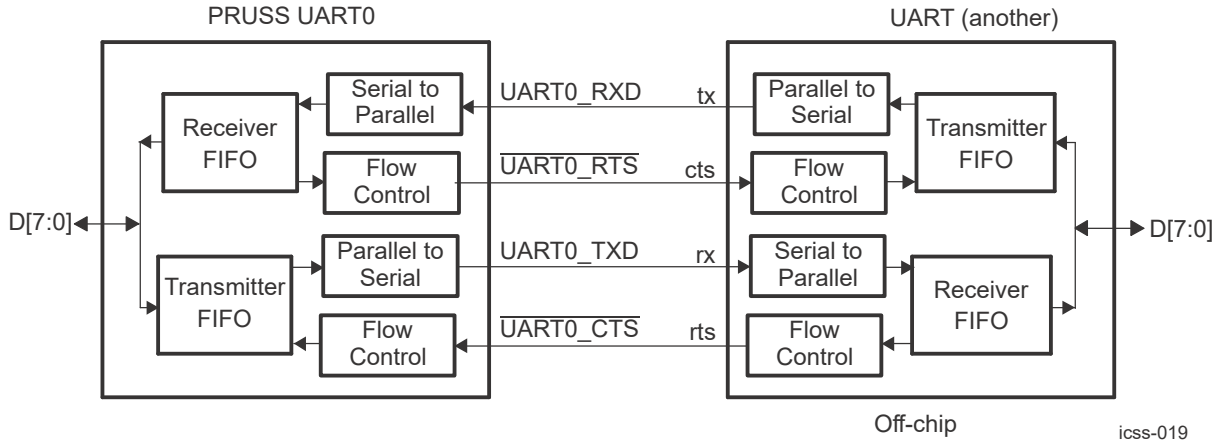

Figure 7-49. UART Interface Using Autoflow Diagram

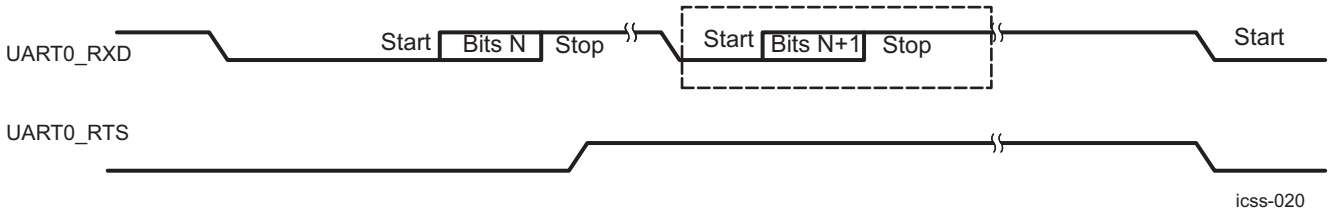
7.4.7.3.7.2.1 PRUSS UART Signal $\overline{\text{UART0_RTS}}$ Behavior

$\overline{\text{UART0_RTS}}$ data flow control originates in the receiver block (see Figure 7-47). When the receiver FIFO level reaches a trigger level of 1, 4, 8, or 14 (see Figure 7-50), $\overline{\text{UART0_RTS}}$ is deasserted. The sending UART may send an additional byte after the trigger level is reached (assuming the sending UART has another byte to send), because it may not recognize the deassertion of $\overline{\text{UART0_RTS}}$ until after it has begun sending the additional byte. For trigger level 1, 4, and 8, $\overline{\text{UART0_RTS}}$ is automatically reasserted once the receiver FIFO is emptied. For trigger level 14, $\overline{\text{UART0_RTS}}$ is automatically reasserted once the receiver FIFO drops below the trigger level.



A. N = Receiver FIFO trigger level.

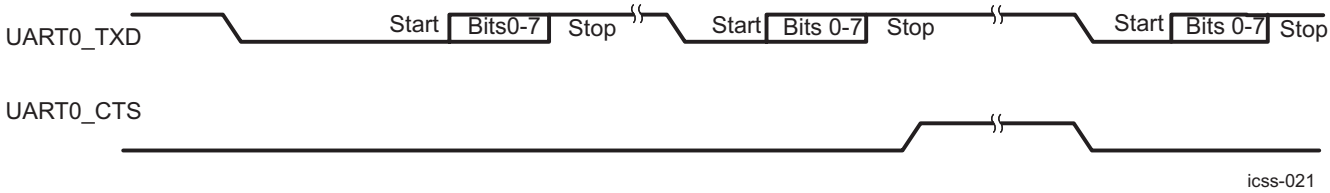
Copyright © 2024 Texas Instruments Incorporated

B. The two blocks in dashed lines cover the case where an additional byte is sent.

Figure 7-50. Autoflow Functional Timing Waveforms for UART0_RTS

7.4.7.3.7.2.2 PRUSS UART Signal UART0_CTS Behavior

The transmitter checks UART0_CTS before sending the next data byte. If UART0_CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, UART0_CTS must be released before the middle of the last STOP bit that is currently being sent (see Figure 7-51). When flow control is enabled, UART0_CTS level changes do not trigger interrupts because the device automatically controls its own transmitter. Without autoflow control, the transmitter sends any data present in the transmitter FIFO and a receiver overrun error may result.



A. When UART0_CTS is active (low), the transmitter keeps sending serial data out.
B. When UART0_CTS goes high before the middle of the last STOP bit of the current byte, the transmitter finishes sending the current byte but it does not send the next byte.
C. When UART0_CTS goes from high to low, the transmitter begins sending data again.

Figure 7-51. Autoflow Functional Timing Waveforms for UART0_CTS

7.4.7.3.7.3 PRUSS UART Loopback Control

The PRUSS UART0 can be placed in the diagnostic mode using the [4]LOOP bit in the modem control register - UART_MCTR, which internally connects the PRUSS UART0 output back to the PRUSS UART0's input. In this mode, the transmit and receive data paths, the transmitter and receiver interrupts, and the modem control interrupts can be verified without connecting to another UART.

7.4.7.3.8 PRUSS UART Emulation Considerations

The [0]FREE bit in the power and emulation management register (UART_PWR) determines how the PRUSS UART0 responds to an emulation suspend event such as an emulator halt or breakpoint. If bit UART_PWR[0] FREE = 0h and a transmission is in progress, the PRUSS UART0 halts after completing the one-word transmission; if bit UART_PWR[0] FREE = 0h and a transmission is not in progress, the PRUSS UART0 halts immediately. If UART_PWR[0] FREE = 1h, the PRUSS UART0 does not halt and continues operating normally.

Note also that most emulator accesses are transparent to PRUSS UART0 operation. Emulator read operations do not affect any register contents, status bits, or operating states, with the exception of the interrupt identification register (UART_INT_FIFO). Emulator writes, however, may affect register contents and may affect PRUSS UART0 operation, depending on what register is accessed and what value is written.

The PRUSS UART0 registers can be read from or written to during emulation suspend events, even if the PRUSS activity has stopped.

7.4.7.3.9 PRUSS UART Exception Processing

7.4.7.3.9.1 PRUSS UART Divisor Latch Not Programmed

Since the processor reset signal has no effect on the divisor latch, the divisor latch will have an unknown value after power up. If the divisor latch is not programmed after power up, the baud clock (BCLK) will not operate and will instead be set to a constant logic 1 state.

The divisor latch values should always be reinitialized following a processor reset.

Copyright © 2024 Texas Instruments Incorporated

7.4.7.3.9.2 Changing Operating Mode During Busy Serial Communication of PRUSS UART

Since the serial link characteristics are based on how the control registers are programmed, the PRUSS UART0 module will expect the control registers to be static while it is busy engaging in a serial communication. Therefore, changing the control registers while the module is still busy communicating with another serial device will most likely cause an error condition and should be avoided.

7.4.8 PRUSS ECAP Module

7.4.8.1 PRUSS eCAP Overview

7.4.8.1.1 Purpose of the PRUSS eCAP Peripheral

The device PRUSS integrated **enhanced capture (eCAP)** module targets:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

7.4.8.1.2 PRUSS eCAP Features

The device PRUSS integrated eCAP module (signified as PRUSS1_eCAP_0 throughout the *PRUSS eCAP Module* section) includes the following features:

- 32-bit time base counter
- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

7.4.8.2 PRUSS ECAP Functional Description

For full description of the PRUSS ECAP0 module and functionality, refer to the *Enhanced Capture (eCAP) Module.*

7.4.8.2.1 PRUSS Capture and APWM Operating Mode

The PRUSS1_eCAP_0 module resources can be used to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The PRUSS_ECAP_CAP1 and PRUSS_ECAP_CAP2 registers become the active period and compare registers, respectively, while PRUSS_ECAP_CAP3 and PRUSS_ECAP_CAP4 registers become the period and capture shadow registers, respectively. Figure 7-52 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

A. A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
B. In APWM mode, writing any value to PRUSS_ECAP_CAP1/PRUSS_ECAP_CAP2 active registers also writes the same value to the corresponding shadow registers PRUSS_ECAP_CAP3/PRUSS_ECAP_CAP4. This emulates immediate mode. Writing to the shadow registers PRUSS_ECAP_CAP3/PRUSS_ECAP_CAP4 invokes the shadow mode.

Figure 7-52. PRUSS Capture and APWM Modes of Operation

7.4.9 PRUSS IEP

This section describes the Industrial Ethernet Peripheral (IEP) Module which is part of the PRUSS.

7.4.9.1 PRUSS IEP Overview

The Industrial Ethernet Peripheral (IEP) performs hardware work required for Industrial Ethernet functions. The IEP module features an industrial ethernet timer with 16 compare events, industrial ethernet sync generator and latch capture, industrial ethernet watchdog timer, and a digital I/O port (DIGIO).

7.4.9.2 PRUSS IEP Functional Description

This section provides the functional description of the IEP component. The PRUSS module implements one Industrial Ethernet Peripheral (IE0). The IEP functional block diagram is shown in Figure 7-53.

n = 0

Figure 7-53. IEP Functional Block Diagram

7.4.9.2.1 PRUSS IEP Clock Generation

The IEP has a selectable module input clock (PRU_ICSS_IEP_CLK, see also *PRUSS in Module Integration*). The clock source is selected by the state of the CTRLMMR_PRU_ICSS_CLKSEL[19-16] IEP_CLKSEL bit within the CTRL_MMR0 register space. Two clock sources are supported for the IEP input clock:

- PRU_ICSS_IEP_CLK (where n = 0 or 1): The source clock for IEP module can be selected through IEP Clock Multiplexer (see also *PRUSS in Module Integration*). The default functional source clock for IEP is MAIN_PLL3_HSDIV1_CLKOUT, derived from PLL3 HSDIV1. The IEP functional clock (PRU_ICSS_IEP_CLK) runs at 200 or 250 MHz.
- PRU_ICSS_ICLK (where n = 0 or 1): The PRUSS interface clock is derived as divided version of the device PLLCTRL output clock (SYSCLK0/2).

Switching from PRU_ICSS_IEP_CLK to PRU_ICSS_ICLK is done by writing 1h to the PRU_ICSS_IEPCLK_REG/PRU_ICSS0_IEPCLK_REG[0] IEP_OCP_CLK_EN bit. This is a one time configuration step before enabling the IEP function. Switching back from PRU_ICSS_ICLK to PRU_ICSS_IEP_CLK is only supported through a hardware reset of the PRUSS.

CAUTION

When software enables the clock (at PRUSS level) to the IEP module clock input via setting bit PRU_ICSS_IEPCLK_REG/PRU_ICSS0_IEPCLK_REG[0] IEP_OCP_CLK_EN to 1h in the PRUSS_CFG space, there must be NO in-flight transactions to the IEP block.

CAUTION

Switching from PRU_ICSS_IEP_CLK (the IEP specific functional clock source) to the PRU_ICSS_CORE_CLK source is supported ONLY in software. Switching back from PRU_ICSS_CORE_CLK to PRU_ICSS_IEP_CLK is ONLY supported via assertion of a hardware reset to the PRUSS.

7.4.9.2.2 PRUSS IEP Timer

The IEP timer is a simple 64-bit timer. This timer is intended for use by industrial ethernet functions but can also be leveraged as a generic timer in other applications.

7.4.9.2.2.1 PRUSS IEP Timer Features

The IEP timer supports the following features:

- One controller 64-bit count-up counter with an overflow status bit.
  - Runs on ICSS_IEP_CLK or ICSS_ICLK clock.
  - Write 1h to clear status.

Copyright © 2024 Texas Instruments Incorporated

  - Supports a programmable increment value from 1 to 16 (default 5).
  - An optional compensation method allows the increment value to apply compensation increment value from 1 to 16 count up to 2^{24} ICSS_IEP_CLK events with additional slow compensation mode.
- 10× 64-bit capture registers:
  - 8 capture inputs, with optional synchronous or asynchronous mode:
    - 6× rise capture registers: ICSS_IEP_CAPRi_REG0/ IEP_CAPRi_REG1 (where i=0 to 5)
    - 2× rise and fall capture registers: IEP_CAPR6_REG0/ IEP_CAPR6_REG1 and IEP_CAPR7_REG0/ IEP_CAPR7_REG1, each combined with a fall capture - IEP_CAPF6_REG0/ IEP_CAPF6_REG1 and IEP_CAPF7_REG0/ IEP_CAPF7_REG1, respectively
    - One global event (any capture event) output for interrupt
- 16× 64-bit compare registers: IEP_CMPj_REG0/ IEP_CMPj_REG1 (where j = 0 to 15) and IEP_CMP_STATUS_REG[15-0] CMP_STATUS
  - 16 status bits, write 1h to clear
  - 16 individual event outputs
  - One global event output for interrupt generation triggered by any compare event
- 32 outputs, one high-level and one high-pulse for each compare hit event
- IEP_CMP_CFG_REG[0] CMP0_RST_CNT_EN, if enabled, resets the controller counter on the next ICSS_IEP_CLK/ ICSS_ICLK cycle
- Controller counter reset-state is programmable
- Optional 32-bit shadow mode of operation, which can be configured through IEP_CMP_CFG_REG[17] SHADOW_EN bit

7.4.9.2.3 32-Bit Shadow Mode

The IEP module can be configured in 32-bit shadow mode when IEP_CMP_CFG_REG[17] SHADOW_EN bit is set to 1h (default value is 0h, e.g. 64-bit mode of operation is enabled). In this mode, the controller counter will be in 32-bit mode of operation. This enables the shadow copy functionality of the compare registers.

Rules of operation:

1. Switching the state of the controller counter from 32-bit Shadow mode to 64-bit mode of operation, the counter should be disabled and bit IEP_CMP_CFG_REG[17] SHADOW_EN should be cleared to 0h (default value).
2. A new compare update (IEP_CMP_CFG_REG[16-1] CMP_EN = 1h - enables CMP[0:15] event, where [0]CMP_EN maps to CMP0) should be set 4 cycle counts before the next rollover or reset of the counter and to insure the correct shadow copy to active update is correct.

Sequence of operation:

1. Disable counter trough IEP_GLOBAL_CFG_REG[0] CNT_ENABLE = 0h (default value).
2. Clear controller counter through IEP_CMP_CFG_REG[17] SHADOW_EN = 0h (64-bit mode of operation)
3. Enable 32-bit Shadow mode through IEP_CMP_CFG_REG[17] SHADOW_EN bit (value: 1h)
4. Program IEP_CMPm_REGn (where m = 0 to 15 and n = 0 to 1); use the upper 32-bits (IEP_CMP0_REG1[31-0] CMP0_1) of the 64-bit CMP
   a. The lower 32-bits are the active compare value (IEP_CMPm_REG0[31-0] CMPm_0, where m = 0 to 15), software can only read this bits
   b. The upper 32-bits are the shadow copy (IEP_CMPm_REG1[31-0] CMPm_1, where m = 0 to 15), software can write and read this bits
5. Enable counter trough IEP_GLOBAL_CFG_REG[0] CNT_ENABLE = 1h

After the counter is enabled, then software can load a new set of CMP[0:15] without affecting the current active values of (IEP_CMPm_REG0[31-0] CMPm_0, where m = 0 to 15). Only when the counter is reset to 32-bit Shadow mode (IEP_CMP_CFG_REG[17] SHADOW_EN = 1h), it will load the shadow copy of IEP_CMPm_REG1[31-0] CMPm_1 into local copy.

Shadow compare value (IEP_CMPm_REG1[31-0] CMPm_1) is loaded into active register IEP_CMPm_REG0[31-0] CMPm_0 when the controller counter is configured in 32-bit Shadow mode. If

Copyright © 2024 Texas Instruments Incorporated

IEP_CMP_CFG_REG[0] CMP0_RST_CNT_EN bit is enabled (value 1h) to reset the counter, the next reset event will be defined by the last CMP0 update.

7.4.9.2.4 PRUSS IEP Timer Basic Programming Sequence

Follow these basic steps to configure the IEP Timer.

Counter maintains/function:

1. Once enabled, the counter will count every PRU_ICSS_IEP_CLK cycle, default rate of 200 MHz.
2. It is a free running counter with a sticky over flag status bit.
3. The counter over flow flag (IEP_GLOBAL_STATUS_REG[0] CNT_OVF) will get set when the counter switches/rollsover from 0xFFFF_FFFF to 0x0000_0000.
4. The counter will continue to count up. The software will need to read/clear the counter over flow flag and increment the MSB in software variable.

Compare function:

1. Initialize timer to known state (default values)
   - Disable counter (IEP_GLOBAL_CFG_REG[0] CNT_ENABLE = 0)
   - Reset Count Register (IEP_COUNT_REG0, IEP_COUNT_REG1) by writing FFFFFFFFh to clear
   - Clear overflow status register (IEP_GLOBAL_STATUS_REG[0] CNT_OVF = 1)
   - Clear compare status (IEP_CMP_STATUS_REG[15-0] CMP_STATUS) by writing FFFFFFFFh to clear
2. Set compare values IEP_CMPj_REG0, IEP_CMPj_REG1 (where j = 0 to 15)
3. Enable compare events (IEP_CMP_CFG_REG[16-1] CMP_EN = 1)
4. Set increment value (IEP_GLOBAL_CFG_REG[7-4] DEFAULT_INC)
5. Set compensation value (IEP_COMPEN_REG[22-0] COMPEN_CNT)
6. Enable counter (IEP_GLOBAL_CFG_REG[0] CNT_ENABLE = 1)

Capture function:

1. Update/Enable the counter if required
2. Program the enable the desired capture event
3. Wait for global capture event
4. Read/Clear the capture status to determine which capture event occurred
5. Read the capture count

7.4.9.2.5 Industrial Ethernet Mapping

Some of the capture inputs and compare registers are mapped to specific industrial Ethernet functions in hardware, shown in Table 7-74. All capture inputs are mapped to industrial Ethernet functions, and these inputs are not available for any other application. The CMP1 and CMP2 compare registers also function as the start time triggers for SYNC0 and SYNC1, respectively.

Table 7-74. IEP Timer Mode Mapping

Capture Input	IEP Line/Function
IEP_CAPR0_REG0/ IEP_CAPR0_REG1, rise only	If EXT_CAP_EN[0] = 0h (Internal source is selected)/ PRU0_RX_SOF If EXT_CAP_EN[0] = 1h (External source is selected)/ ICSS_IEP_CAP_INTR_REQ0
IEP_CAPR1_REG0/ IEP_CAPR1_REG1, rise only	If EXT_CAP_EN[1] = 0h (Internal source is selected)/ PRU0_RX_SFD If EXT_CAP_EN[1] = 1h (External source is selected)/ ICSS_IEP0_CAP_INTR_REQ1
IEP_CAPR2_REG0/ IEP_CAPR2_REG1, rise only	If EXT_CAP_EN[2] = 0h (Internal source is selected)/ PRU1_RX_SOF If EXT_CAP_EN[2] = 1h (External source is selected)/ ICSS_IEP_CAP_INTR_REQ2

Table 7-74. IEP Timer Mode Mapping (continued)

Capture Input	IEP Line/Function
IEP_CAPR4_REG0/ IEP_CAPR4_REG1, rise only	If EXT_CAP_EN[4] = 0h (Internal source is selected)/ PORT0_TX_SOF; For MII mode uses loopback for lower jitter 40ns versus 4ns. If EXT_CAP_EN[4] = 1h (External source is selected)/ ICSS_IEP_CAP_INTR_REQ4
IEP_CAPR5_REG0/ IEP_CAPR5_REG1, rise only	If EXT_CAP_EN[5] = 0h (Internal source is selected)/ PORT1_TX_SOF For MII mode uses loopback for lower jitter 40ns versus 4ns. If EXT_CAP_EN[5] = 1h (External source is selected)/ ICSS_IEP_CAP_INTR_REQ5
IEP_CAPR6_REG0/ IEP_CAPR6_REG1 - rise and IEP_CAPF6_REG0/ IEP_CAPF6_REG1 - fall	PR_IEP_EDC_LATCH_IN0 (IO inputs at SoC level)
IEP_CAPR7_REG0/ IEP_CAPR7_REG1 - rise and IEP_CAPF7_REG0/ IEP_CAPF7_REG1 - fall	PR_IEP_EDC_LATCH_IN1 (IO inputs at SoC level)
IEP_CMP1_REG0/ IEP_CMP1_REG1	For SYNC0 trigger of start time
IEP_CMP2_REG0/ IEP_CMP2_REG1	For SYNC1 trigger of start time; only valid in the SYNC2 independent mode
IEP_CMP3_REG0/ IEP_CMP3_REG1	For MII TX0 start trigger, if MII register MII_RT_TXCFG0/1[2] TX_EN_MODEn is enabled (where n = 0 or 1).
IEP_CMP4_REG0/ IEP_CMP4_REG1	For MII TX1 start trigger, if MII register MII_RT_TXCFG0/1[2] TX_EN_MODEn is enabled (where n = 0 or 1).

7.4.9.2.6 PRUSS IEP Sync0/Sync1 Module

The industrial ethernet sync block supports the generation of two synchronization signals: SYNC0 and SYNC1. SYNC0 and SYNC1 can be directly mapped to output signals (pr<k>_iep<n>_edc_sync_out0 and pr<k>_iep<n>_edc_sync_out1) for external devices to use. They can also be used for internal synchronization within the PRUSS. These signals are also mapped as system events and can therefore be mapped to the Arm core's Host interrupts.

7.4.9.2.6.1 PRUSS IEP Sync0/Sync1 Features

The industrial ethernet sync block supports the following features:

- Two synchronize generation signals (SYNC0, SYNC1)
  - Activation time synchronized with IEP Timer
- IEP_CMP1_REG0/ IEP_CMP1_REG1 triggers SYNC0 activation time
- IEP_CMP2_REG0/ IEP_CMP2_REG1 triggers SYNC1 activation time (only valid in the SYNC2 independent mode)
  - Pulse width defined by registers or acknowledge mode (remain asserted until software acknowledged)
  - Cyclic or single-shot operation
  - Option to enable or disable sync generation
- Programmable number of clock cycles between the start of SYNC0 to the start of SYNC1

7.4.9.2.6.2 PRUSS IEP Sync0/Sync1 Generation Modes

There are four modes of operation for the sync signals: cyclic mode, single shot mode, cyclic with acknowledge mode, and single shot with acknowledge mode. Figure 7-54 shows examples of these modes. The start time is set by the IEP_SYNC_START_REG[31-0] SYNC_START bit field. The cycle time is configured by the IEP_SYNC0_PERIOD_REG[31-0] SYNC0_PERIOD bit field. The pulse length is defined by IEP_SYNC_PWIDTH_REG[31-0] SYNC_HPW bit field.

Copyright © 2024 Texas Instruments Incorporated

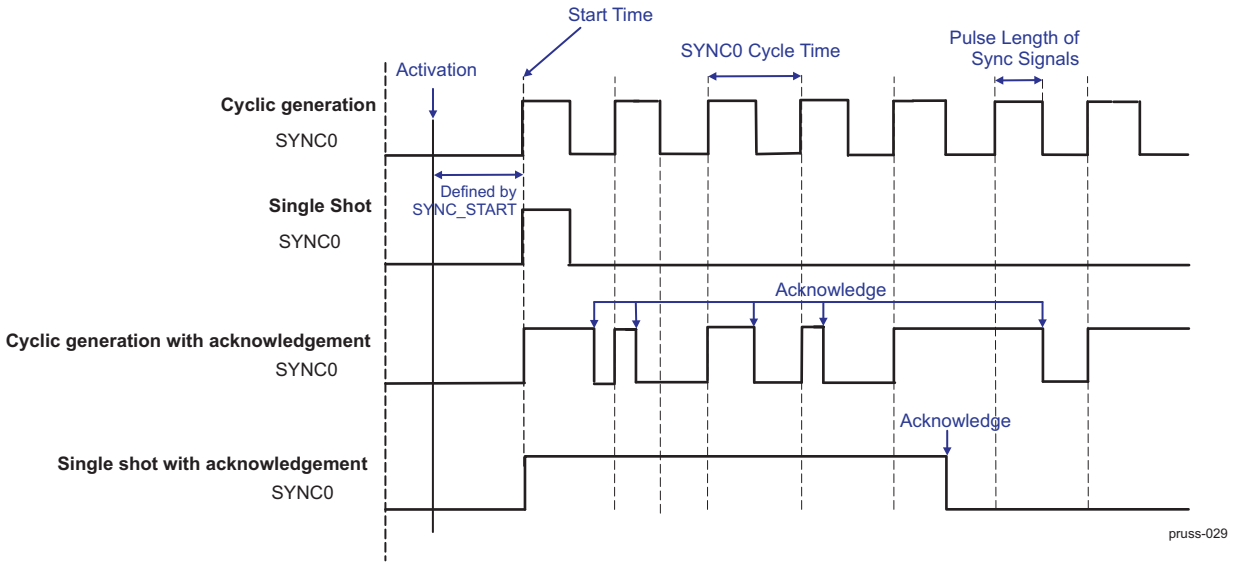

Figure 7-54. PRUSS IEP SYNC0 Signal Generation Modes

In SYNC1 dependent mode (IEP_SYNC_CTRL_REG[8] SYNC1_IND_EN = 0h), SYNC1 depends on SYNC0 and the start time of the SYNC1 can be defined by the IEP_SYNC1_DELAY_REG register. Figure 7-55 shows different examples when changing the value in the IEP_SYNC1_DELAY_REG register. Note: If the SYNC1 delay time is 0, SYNC1 reflects SYNC0. Cyclic generation cannot be used for network time synchronized applications because only the CMP1/CMP2 hit occurs in the compensated time domain.

Copyright © 2024 Texas Instruments Incorporated

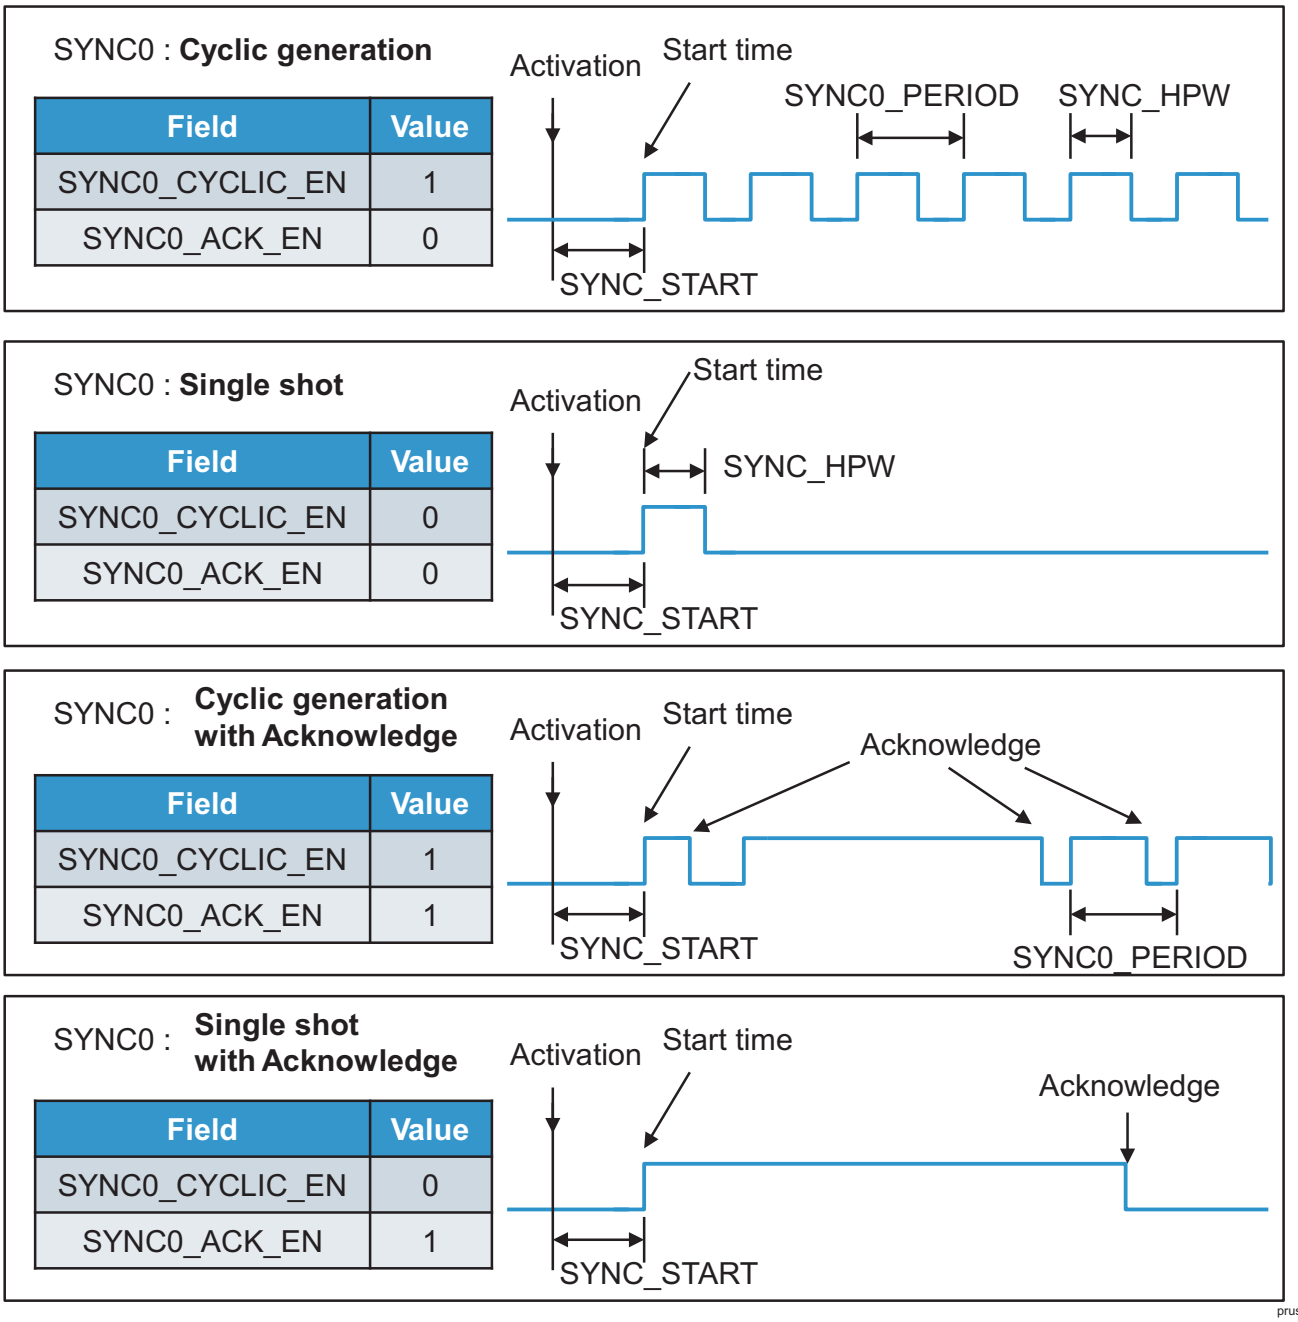

Figure 7-55. Examples of the Dependent Mode of SYNC1

7.4.9.2.7 PRUSS IEP WatchDog

In industrial ethernet applications, the watchdog timer (WD) is used to monitor process data communication and to turn off the outputs of the digital input/output (DIGIO) functional block after a set time. The WD will thereby protect the system from errors or faults by timeout or expiration. The expiration is used to initiate corrective action in order to keep the system in a safe state and restore normal operation based on configuration. Therefore, if the system is stable, the watchdog timer should be regularly reset or cleared to avoid timeout or expiration.

The IEP watchdog timer supports the following features:

- One 16-bit pre-divider for generating a WD clock (default 100µs) based on PRU_ICSS_IEP_CLK input

Copyright © 2024 Texas Instruments Incorporated

- Two 16-bit Watchdog Timers:
  - PDI_WD for Sync Managers WD, used in conjunction with digital input/output (DIGIO)
  - PD_WD for data link layer user WD, used in conjunction with data link layer or application layer interface actions

Note

For more details on the PRUSS Industrial Ethernet Watchdog timer, refer also to the Watchdog timer register descriptions covered in the ICSSM Registers,

7.4.9.2.8 PRUSS IEP DIGIO

The IEP digital I/O (DIGIO) block provides dedicated I/Os for industrial ethernet protocols. The digital inputs can be sampled when specific events occur or continuously as a raw input. Likewise, driving the digital outputs can be triggered by specific events or controlled by software. The timing, delay cycle clocks, data sources, and data valid of the digital input and outputs are controlled by the IEP_DIGIO_CTRL_REG and IEP_DIGIO_EXP_REG registers. Additionally, the IEP DIGIO block can be used as generic I/Os in other applications.

7.4.9.2.8.1 PRUSS IEP DIGIO Features

The IEP digital I/O supports the following features:

- Digital data output:
  - 4 channels (PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28])
  - Five event options for driving output data output:
    - End of frame event (PRU0/1_RX_EOF)
    - SYNC0 events
    - SYNC1 events
    - Watchdog trigger
    - Software enable
- Digital data out enable (optional tri-state control)
- Digital data input:
  - 4 channels (PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28])
  - IEP_DIGIO_DATA_IN_RAW_REG supports direct sampling of PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28]
  - IEP_DIGIO_DATA_IN_REG supports four event options to trigger sampling of PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28]:
    - Start of frame event in start of frame (SOF) mode
    - pr<k>_iep<n>_edc_latch_in<0/1> event
    - SYNC0 events: pr<k>_iep<n>_edc_sync_out0
    - SYNC1 events: pr<k>_iep<n>_edc_sync_out1

The industrial digital I/Os supported by the PRUSS IEP peripheral are described in Table 7-75.

Table 7-75. PRUSS IEP Digital IOs

7.4.9.2.8.3 PRUSS IEP DIGIO Block Diagrams

Figure 7-56 shows the signals and registers for capturing the DIGIO data in. Note that bit field [5-4]IN_MODE in the IEP_DIGIO_CTRL_REG register must be set to 1h for data to be latched on the external PR<k>_IEP<n>_EDC_LATCH_IN0 signal. In PRU0/1_RX_SOF mode, the delay time of capturing PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28] is programmable through the [11-8]SOF_DLY bit of the IEP_DIGIO_EXP_REG register.

Copyright © 2024 Texas Instruments Incorporated

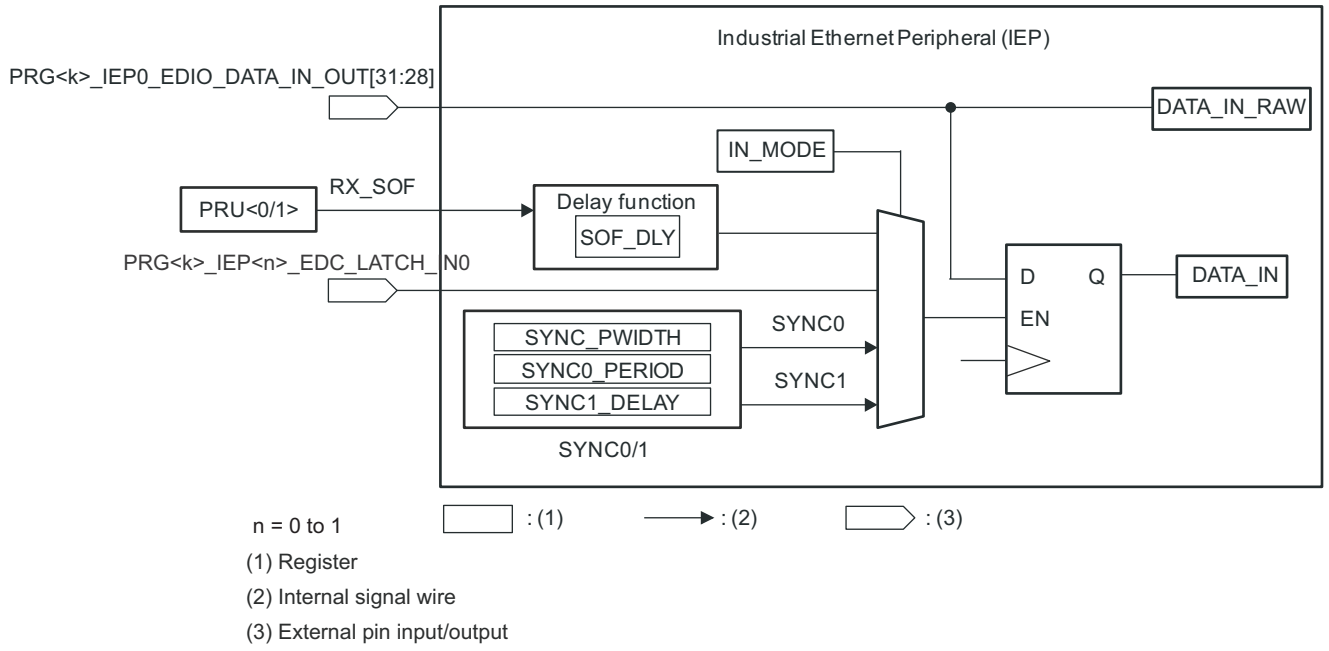

Figure 7-56. IEP DIGIO Data In

Figure 7-57 shows the signals and registers for driving the DIGIO data out.

The PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28] is immediately forced to zero when IEP_DIGIO_CTRL_REG[1] OUTVALID_MODE = 1h, pr1_edio_oe_ext = 1h, and pd_wd_exp = 1h, or the next update hardware post pd_wd_exp. Delay assertion of PR<k>_IEP0_EDIO_OUTVALID from PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28] update events are controlled by software through IEP_DIGIO_EXP_REG[2] SW_OUTVALID.

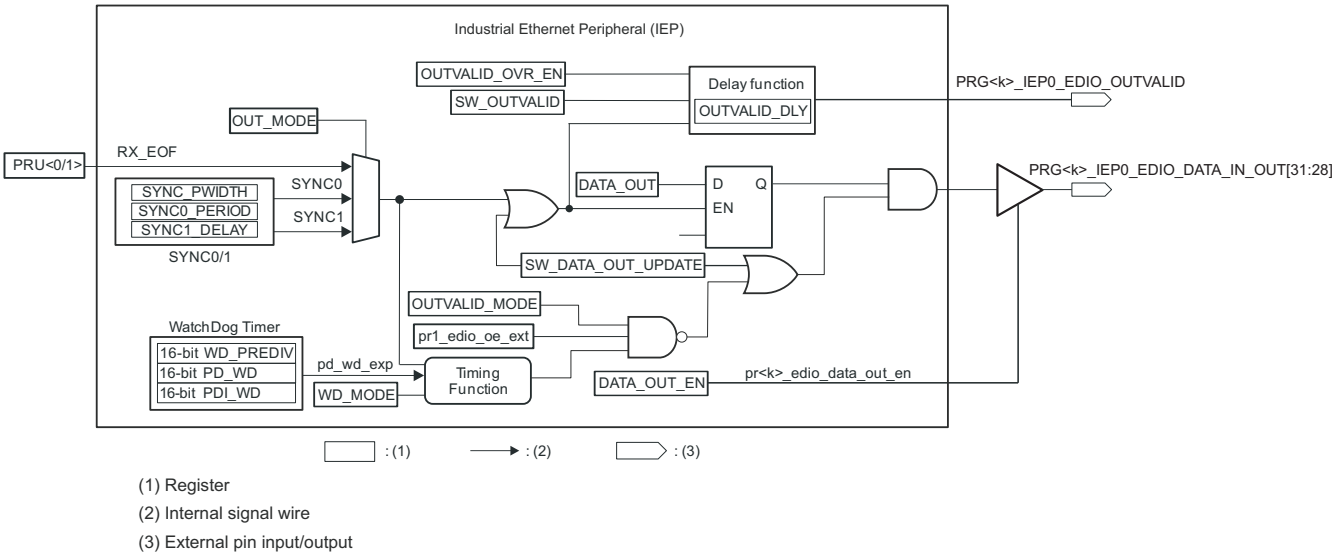

Figure 7-57. IEP DIGIO Data Out

7.4.9.2.8.4 PRUSS IEP Basic Programming Model

Follow these steps to configure and read the DIGIO Data Input:

1. Read IEP_DIGIO_DATA_IN_RAW_REG for raw input data

or

Copyright © 2024 Texas Instruments Incorporated

1. Enable sampling of PR<k>_IEP0_EDIO_DATA_IN_OUT[31:28] by setting IEP_DIGIO_CTRL_REG[5-4] IN_MODE = 1h.
2. Read IEP_DIGIO_DATA_IN_REG for data sampled upon PR<k>_IEP<n>_EDC_LATCH_IN0 posedge

Follow these steps to configure and write to the DIGIO Data Output:

1. Pre-configure DIGIO by setting IEP_DIGIO_EXP_REG[1] OUTVALID_OVR_EN and IEP_DIGIO_EXP_REG[0] SW_DATA_OUT_UP
2. Write to IEP_DIGIO_DATA_OUT_REG to configure output data.
3. To HiZ output, set corresponding IEP_DIGIO_DATA_OUT_EN_REG[31-0] DATA_OUT_EN bits to 1h (clear to 0h to drive value stored in IEP_DIGIO_DATA_OUT_REG).

Chapter 8

Interprocessor Communication (IPC)

This chapter describes the interprocessor communication (IPC) modules in the device.

8.1 Inter-processor Communication Scheme (IPC) 787

Copyright © 2024 Texas Instruments Incorporated

8.1 Inter-processor Communication Scheme (IPC)

Device has multiple hardware mechanisms to provide inter-processor level communication.

Copyright © 2024 Texas Instruments Incorporated

8.1.1 Mailbox

This chapter describes the Mailbox module of the device.

8.1.1.1 Mailbox Overview

Mailbox module serves to facilitate the communication between the various on-chip processors of the device by providing a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors (users) through a set of registers and associated interrupt signals.

8.1.1.1.1 Mailbox Features

Each mailbox module supports the following features:

- Parameters configured at design time:
  - Number of mailbox clusters
    - Each mailbox cluster has the same configuration
    - Clusters are accessed via separate VBUS regions. Clusters can be treated as mailbox module instances.
  - Number of users
  - Number of mailbox message queues
  - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Partial writes do not advance the FIFO pointers
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

Note

Some features may not be available. See *Module Integration* for more information.

Copyright © 2024 Texas Instruments Incorporated

8.1.1.2 Mailbox Functional Description

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQ_ENABLE_SET_j (or MAILBOX_IRQ_ENABLE_CLR_j) register.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each MAILBOX_IRQ_STATUS_RAW_j/MAILBOX_IRQ_STATUS_CLR_j interrupt status register corresponds to a particular user.

8.1.1.2.1 Mailbox Block Diagram

Figure 8-1 shows the mailbox internal block diagram.

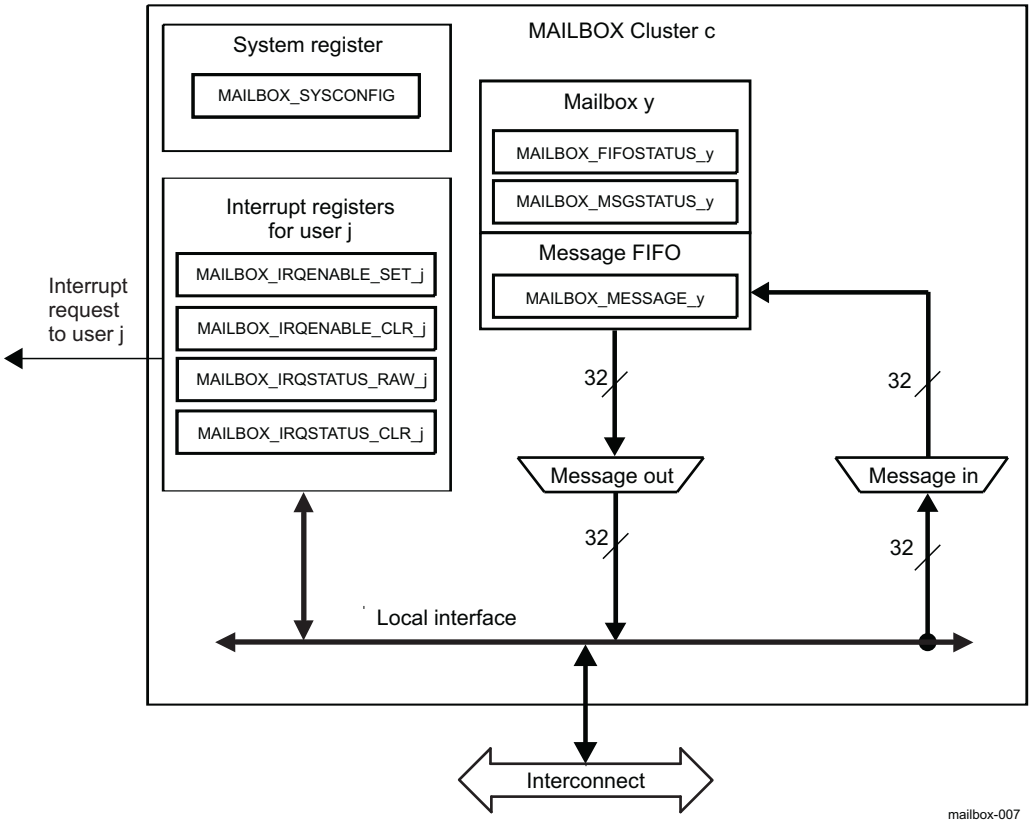

Figure 8-1. Mailbox Block Diagram

c = 0 to 11

j = 0 to 3

y = 0 to 15

8.1.1.2.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

Copyright © 2024 Texas Instruments Incorporated

8.1.1.2.3 Mailbox Power Management

The clkstop_idle will be asserted if all of the following are true:

- The VBUSP interface is inactive
- All mailboxes are empty
- There are no enabled events or outstanding interrupts

An enabled event means there is pending action required from one of the users, and it means one or more mailboxes still expect data.

8.1.1.2.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

Table 8-1 lists the event flags, and their mask, that can cause module interrupts.

Table 8-1. Interrupt Events

Non-Maskable Event Flag(1)	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQ_STATUS_RAW_j[0+y*2] NEWMSGSTATUSMBy	MAILBOX_IRQ_STATUS_CLR_j[0+y*2] NEWMSG_STATUSMBy	MAILBOX_IRQ_ENABLE_CLR_j[0+y*2] NEWMSG_STATUSMBy	MAILBOX_IRQ_ENABLE_SET_j[0+y*2] NEWMSG_STATUSMBy	Mailbox *y* receives a new message.
MAILBOX_IRQ_STATUS_RAW_j[1+y*2] NOTFULLSTATUSMBy	MAILBOX_IRQ_STATUS_CLR_j[1+y*2] NOTFULLSTATUSMBy	MAILBOX_IRQ_ENABLE_CLR_j[1+y*2] NOTFULLSTATUSMBy	MAILBOX_IRQ_ENABLE_SET_j[1+y*2] NOTFULLSTATUSMBy	Mailbox *y* message queue is not full.

(1) MAILBOX_IRQ_STATUS_RAW_j register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQ_STATUS_CLR_j register.

Writing a logical 1 in a bit of the MAILBOX_IRQ_STATUS_CLR_j register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQ_STATUS_RAW_j register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQ_ENABLE_SET_j register. Events are reported in the appropriate MAILBOX_IRQ_ENABLE_CLR_j and MAILBOX_IRQ_STATUS_RAW_j registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQ_ENABLE_CLR_j register. Events are only reported in the appropriate MAILBOX_IRQ_STATUS_RAW_j register.

In case of the MAILBOX_IRQ_STATUS_RAW_j register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

8.1.1.2.5 Mailbox Assignment

8.1.1.2.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQ_ENABLE_SET_j register. The receiver reads the MAILBOX_MESSAGE_y register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFO_STATUS_y and/or MAILBOX_MSG_STATUS_y registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

Copyright © 2024 Texas Instruments Incorporated

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQ_ENABLE_SET_j register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFO_STATUS_y or MAILBOX_MSG_STATUS_y registers
- Write the message to the corresponding MAILBOX_MESSAGE_y register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQ_ENABLE_SET_j register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQ_STATUS_CLR_j register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQ_STATUS_CLR_j register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

8.1.1.2.6 Sending and Receiving Messages

8.1.1.2.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_y register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX_FIFO_STATUS_y register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX_MESSAGE_y register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_y register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSG_STATUS_y register.

8.1.2 Spinlock

This chapter describes the Spinlock module of the device.

8.1.2.1 Spinlock Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device.

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 8-3 shows an overview of the Spinlock module.

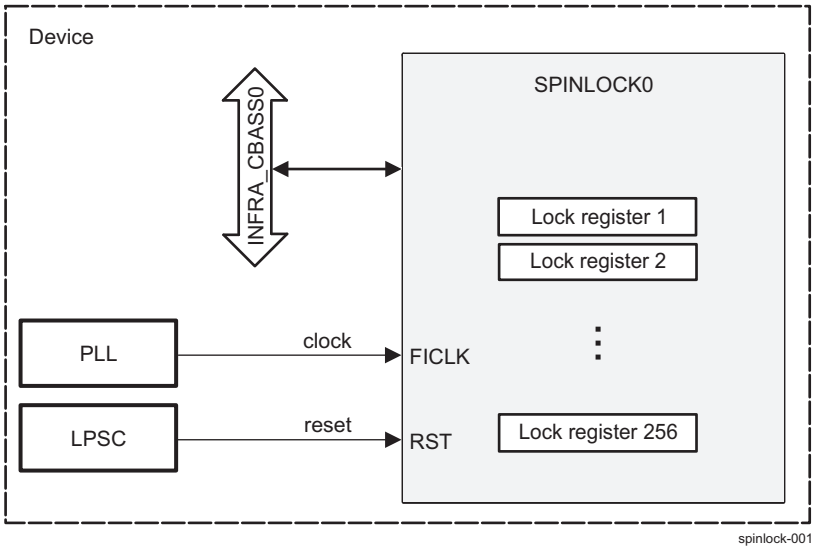

Figure 8-3. Spinlock Overview

Note

Some features may not be available. See *Module Integration* for more information.

8.1.2.2 Spinlock Functional Description

8.1.2.2.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The SPINLOCK_SYSTATUS[0] RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

8.1.2.2.2 Spinlock Power Management

The Spinlock module supports the Power Idle interface. Software must arrange to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

1. Software must check that all controllers that may be using the Spinlock module are either:
   a. Already powered off (all in-use flags are 0)
   b. Notified that Spinlock is not available and the notification is acknowledged
2. If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the SPINLOCK_SYSTATUS register. If any locks are held, they are orphaned because they are not held by any controller that is still active. Alternatively, you may decide to wait a timeout period to allow any active controller to clean up its locks before powering down.

Copyright © 2024 Texas Instruments Incorporated

The Spinlock module may now be powered off.

8.1.2.2.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

8.1.2.2.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_y[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_y[0] TAKEN = 0), where y = 0h to FFh.

When the status of lock *y* (where y = 0 to 255) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_y register returns 0 and sets the lock to Taken (locked). When the status of lock *y* is Taken, a read returns 1 and does not change the state of the lock.

A write to the SPINLOCK_LOCK_REG_y register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

Figure 8-4 shows the SPINLOCK_LOCK_REG_y register state diagram.

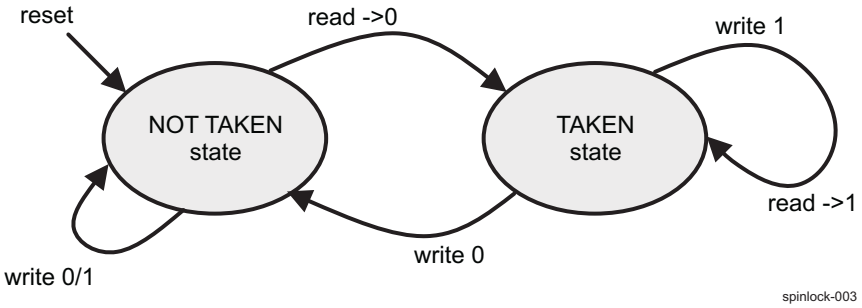

Figure 8-4. Lock Register State Diagram

Copyright © 2024 Texas Instruments Incorporated

Note

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

8.1.2.3 Spinlock Programming Guide

8.1.2.3.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

8.1.2.3.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 8-10. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
LPSC	Spinlock functional and interface clock must be enabled. For more information, see *Clocking*

8.1.2.3.1.2 Basic Spinlock Operations

The main Spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

8.1.2.3.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_y registers at system startup to insure that all locks are initialized to Not Taken.

Table 8-11. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = 1?	SPINLOCK_SYSTATUS[0] IU0	=1
Free the 256 locks	SPINLOCK_LOCK_REG_y[0] TAKEN (y = 0 to 255)	0x0
END		

8.1.2.3.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software must disable interrupts. Then it must read the SPINLOCK_LOCK_REG_y[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it must proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition must be reattempted. To prevent unknown interrupt disabled time, interrupts must be re-enabled and then disabled before reattempting to acquire the lock. Figure 8-5 shows the described above procedure.

8.1.3 Secure Proxy (SEC_PROXY)

The third IPC hardware mechanism is to use SEC_PROXY, which provides an IPC mechanism which carries a large message for complex communications among processors. It allows processors to read and write a message in small chunks.

There are two sets of SEC_PROXY in the device, one SEC_PROXY is dedicated for IPC for HSM M4F, and the second SEC_PROXY is for the rest. When the SEC_PROXY generates events, an IPC message is received or sent, and events are sent to interrupt aggregators before those events are converted into interrupts to the processors. The utilization of SEC_PROXY is user defined through memory map allocation. Each processor can be allocated with its own SEC_PROXY region to receive and send IPC messages.

Chapter 9

Memory Controllers

This chapter describes the memory controllers in the device.

9.1 DDR Subsystem (DDRSS) 802
9.2 Region-based Address Translation (RAT) Module 817

Copyright © 2024 Texas Instruments Incorporated

9.1 DDR Subsystem (DDRSS)

This section describes the DDR Subsystem (DDRSS) for the device.

9.1.1 DDRSS Overview

The DDR subsystem in this device comprises DDR controller, DDR PHY and wrapper logic to integrate these blocks in the device. The DDR subsystem is referred to as DDRSS0 and is used to provide an interface to external SDRAM devices which can be utilized for storing program or data. DDRSS0 is accessed via CBASS0 interconnect.

Table 9-1 shows DDRSS allocation across device domains.

Table 9-1. DDRSS Allocation Across Device Domains

Instance	Domain	
	MCU	MAIN
DDRSS0	-	✓

Figure 9-1 shows an overview of the DDRSS0 and its surrounding modules.

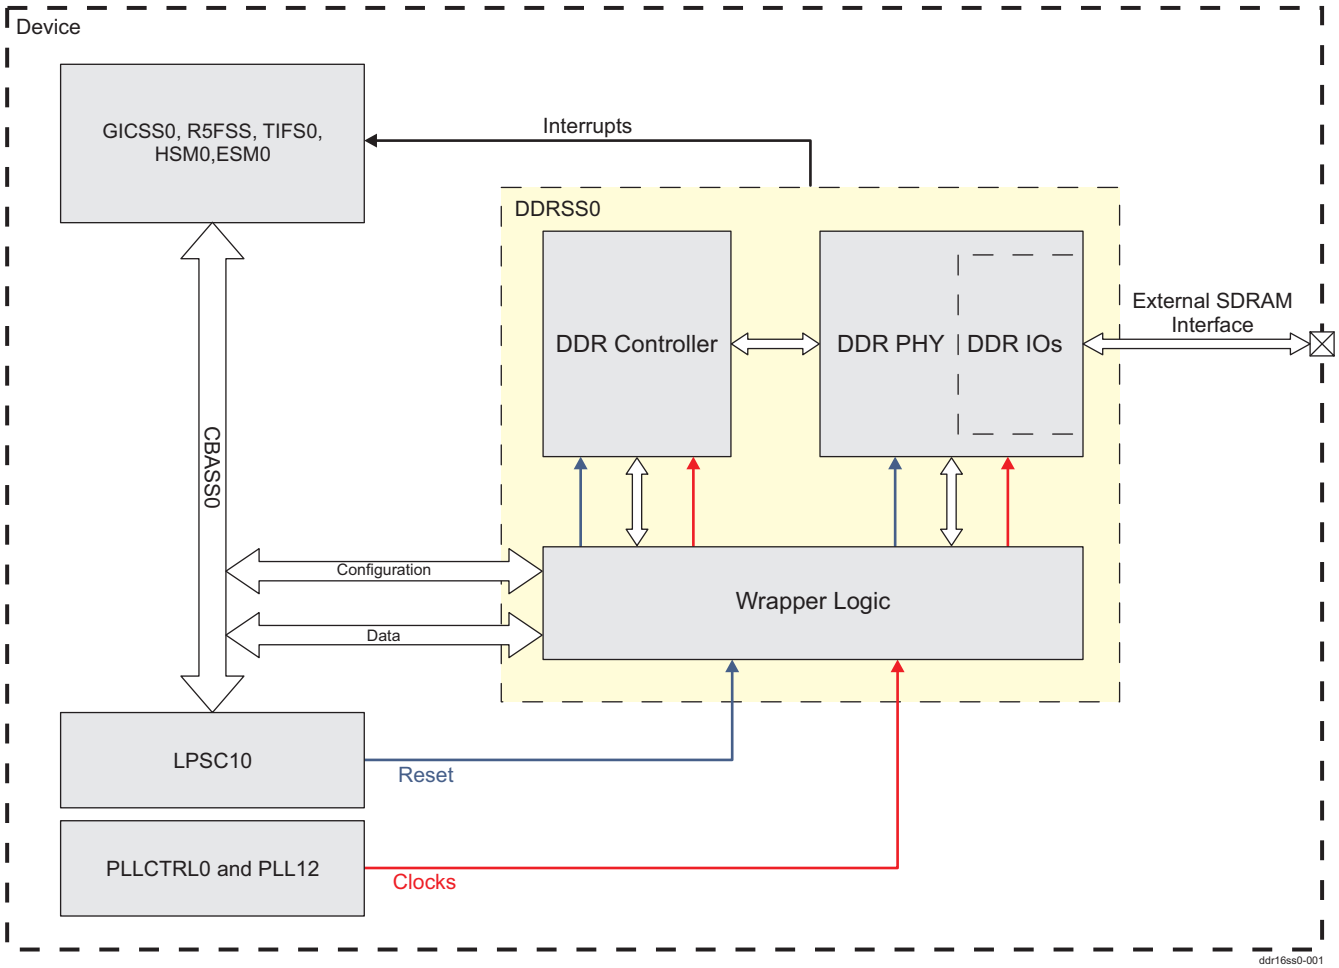

Figure 9-1. DDRSS Overview

The DDRSS0 supports:

- Memory Types:

Copyright © 2024 Texas Instruments Incorporated

  - DDR4 up to 1600Mbps
  - LPDDR4 up to 1600Mbps
- Memory Bus Features:
  - 16-bit width with in-line ECC
  - Up to 2 ranks
  - SDRAM address range up to 8 GB
- System Bus Interface:
  - 128-bit data width
  - Little endian only
  - Address aliasing prevention to block accesses to unpopulated SDRAM region
  - Clock asynchronous to DDR clock
- Configuration Bus Interface:
  - 32-bit data width
  - Linear incrementing addressing mode
  - 32-bit aligned accesses only
  - Little endian only
  - Clock asynchronous to DDR clock
- Key Features:
  - Full coherency across all commands
  - Bank interleaving
  - Priority based scheduling
  - Scheduling based on bank openness
  - Class of Service (CoS) - Three latency classes supported
  - Read/write scheduling to avoid turn-around time
  - Prioritized refresh scheduling
  - Dynamic change of refresh rate via software for extended temperatures
  - Statistical counters for performance management
- SDRAM ECC Features:
  - In-line ECC
  - 32-byte ECC calculated over 256-byte data
  - Read-modify-write ECC for sub-word writes
  - Support ECC cache to improve in-line ECC performance
  - Support 64 cache-lines each 512-byte wide
  - ECC address error logging
  - Statistical counters for counting ECC errors
- Low Power Features:
  - All power modes defined by JEDEC (clock stop for LPDDR4, self-refresh, power-down, etc.)
  - Self-refresh entry and exit via software or hardware clock stop request/acknowledge
  - System bus clock stop via hardware clock stop request/acknowledge when controller is idle
  - Automatic idle power saving mode when no or low activity is detected
  - DDR and system bus clock frequency change using self-refresh via software or hardware clock stop request/acknowledge
  - Turning off SoC power after DDR is put into self-refresh (DDR reset and CKE I/O retention)
  - Tri-stating of all DDR I/O cells via software while driving CKE and RESETn pins during self-refresh
  - LPDDR4 Frequency Set Point (FSP)
- Functional Safety Features:
  - VBUSM2AXI bridge AXI bus timeout
- DDR PHY Features:
  - Automatic and software controllable initialization and calibration (ZQ) for the DDR PHY and I/O cells
  - Automatic and software controllable delay line calibrations with Voltage and Temperature (VT) compensation
  - Automatic and software controllable write levelling with VT compensation

Copyright © 2024 Texas Instruments Incorporated

- Automatic read DQS gate training per rank with VT compensation
- Automatic and software controllable DQ/DQS eye training per rank
- Automatic and software controllable read and write data bit deskew
- Automatic and software controllable Command/Address (CA) levelling with VT compensation for LPDDR4
- Automatic and software controllable CA bit deskew for LPDDR4
- Refreshes to SDRAM during leveling and training
- No seeding requirement based on board topology for any of the leveling and training algorithms
- Dynamic/automatic I/O Receiver disable when read transfer is not on going
- Capability of disabling data macros and I/O cells when not in use

Note

Some features may not be available. See *Module Integration* for more information.

9.1.3 DDRSS Functional Description

9.1.3.1 Class of Service (CoS)

Commands arriving to the DDRSS0 carry the VBUSM priority whereas the DDR controller uses AXI priority. The VBUSM2AXI bridge has the following registers for flexible mapping of the VBUSM priority to DDR controllers's priority:

- Range match registers:
  - DDRSS_V2A_R1_MAT_REG
  - DDRSS_V2A_R2_MAT_REG
  - DDRSS_V2A_R3_MAT_REG
- Priority map registers:
  - DDRSS_V2A_DEF_PRI_MAP_REG
  - DDRSS_V2A_R1_PRI_MAP_REG
  - DDRSS_V2A_R2_PRI_MAP_REG
  - DDRSS_V2A_R3_PRI_MAP_REG

This allows the system to essentially create different classes of service based on the initiator (Route ID) and the priority of the commands.

The priority map registers map the incoming priority to appropriate proirity for the DDR controller as shown in Figure 9-2.

Note

For information about Route ID, see Section 3.1.4, *Route ID* in Chapter 3, *System Interconnect*.

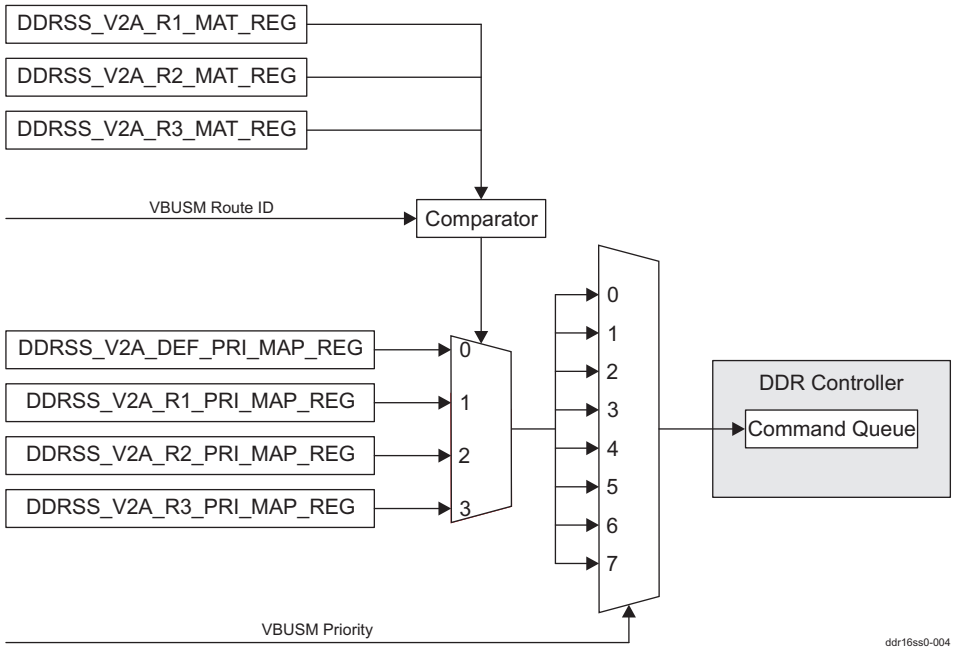

Figure 9-2. DDRSS CoS Mapping Diagram

9.1.3.2 AXI Write Data All-Strobes

The DDR controller data path is connected to the VBUSM2AXI bridge through AXI interface. To enable higher performance and lower latency, the bridge drives the AXI AWALLSTRB signal to a "1" when the AXI write data does not have any byte enable holes. This allows the DDR controller to accept and start processing the write command as soon as possible without waiting for all data. The AXI0_ALL_STROBES_USED_ENABLE bit in

Copyright © 2024 Texas Instruments Incorporated

the DDR Controller must be set to a 0x1 to utilize this feature. The controller ignores the AWALLSTRB signal if AXI0_ALL_STROBES_USED_ENABLE is set to 0x0.

9.1.3.3 Inline ECC for SDRAM Data

For SDRAM data integrity, the VBUSM2AXI bridge supports inline ECC on the data written to or read from the SDRAM. ECC is enabled by programming the bits in the DDRSS_ECC_CTRL_REG register. ECC is stored together with the data so that a dedicated SDRAM device for ECC is not required.

8-bit single error correction double error detection (SECDED) ECC is calculated over 64-bit data quanta. For every 256-byte data block 32 bytes of ECC is stored inline. Thus 1/9th of the total SDRAM space is used for ECC storage and the rest 8/9th is available for system use. From system point of view that 8/9th of the SDRAM data space are seen as consecutive byte addresses. Even if there are non-ECC protected regions the previously described 1/9th-8/9th rule still applies and consecutive byte addresses are seen from system point of view. Note that 8/9 of the total SDRAM space is available for system use regardless of the size of the ECC region(s). In other words, only 8/9 of the memory is available even in non-ECC regions when ECC is enabled.

The ECC is calculated for all accesses that are within the address ranges protected by ECC. The address ranges are specified through the following registers:

- DDRSS_ECC_R0_STR_ADDR_REG
- DDRSS_ECC_R0_END_ADDR_REG
- DDRSS_ECC_R1_STR_ADDR_REG
- DDRSS_ECC_R1_END_ADDR_REG
- DDRSS_ECC_R2_STR_ADDR_REG
- DDRSS_ECC_R2_END_ADDR_REG

Note that the addresses in these address range registers should be in terms of the DDRSS address space, not the SoC memory space. Even though the SoC memory space for DDR may be split into multiple regions, the DDRSS address space is continuous.

For example, if the beginning of DDR is in SoC memory space 0x8000_0000 to 0xFFFF_FFFF, this corresponds to DDRSS address space 0x00000000 to 0x7FFFFFFF. If the SoC has greater DDR address reach, even at a discontinuous address, the address range for these registers would be continuous (eg, if the next DDR address at the SoC level is 0x880000000, the corresponding address would be continuous at 0x80000000)

Note that the value programmed in the ECC range start/end registers does not include the lower 16 bits of the address. For example, to represent an address of 0x40000000, the register contents would be 0x4000.

The ECC is read and verified during reads if both the DDRSS_ECC_CTRL_REG[0] ECC_EN and DDRSS_ECC_CTRL_REG[2] ECC_CK bits are set to 0x1. For 1-bit ECC error, the bridge corrects the data and returns it to the requestor. Although the error is corrected on the returned data, the SDRAM is not corrected. It is responsibility of the system software to correct the ECC error at that location.

It is also responsibility of the system software to pre-load the ECC protected region with known data before functional reads and writes are performed. This can be done by writing to the SDRAM with ECC enabled (DDRSS_ECC_CTRL_REG[0] ECC_EN = 0x1 and DDRSS_ECC_CTRL_REG[1] RMW_EN = 0x1) and ECC check disabled (DDRSS_ECC_CTRL_REG[2] ECC_CK = 0x0). Once the data is loaded in the SDRAM, ECC check must be enabled (DDRSS_ECC_CTRL_REG[2] ECC_CK = 0x1) before using the DDR interface.

9.1.3.3.1 ECC Cache

The VBUSM2AXI bridge implements a 64-line deep ECC cache for improving inline ECC performance. Each cache line can be allocated to an initiator in the system based on its Route ID. The Route ID allocation to cache line can be done by writing to the DDRSS_ECC_RID_INDX_REG and DDRSS_ECC_RID_VAL_REG registers. Since the bridge uses unallocated cache lines for all read accesses without Route ID allocation, one or more locations in the cache should be kept unallocated for better performance. To ensure that at least one cache line remains unallocated, in the case all cache lines are allocated by software, the bridge automatically unallocates the 63rd cache line. Write accesses without Route ID allocation result in ECC and data writes to the SDRAM,

Copyright © 2024 Texas Instruments Incorporated

when the DDRSS_ECC_CTRL_REG[4] WR_ALLOC bit is set to 0x0. When DDRSS_ECC_CTRL_REG[4] WR_ALLOC is set to 0x1, an unassigned cache-line is allocated to write accesses without Route ID allocation.

9.1.3.3.2 ECC Cache Flush

For low power modes, the bridge supports flushing the cache when DDRSS stop clock request is asserted. When a clock stop is requested, the bridge will start issuing writes to the DRAM until all dirty cache locations are written to the DRAM. Once the writes are complete, the bridge asserts an acknowledge signal to let the subsystem know that the operation is complete. The subsystem uses this acknowledge signal along with acknowledgments from other submodules to generate the final DDRSS stop clock acknowledge to the system.

9.1.3.3.3 ECC Statistics

For 1-bit ECC error, the bridge logs the address location for the error in an internal 2-level deep FIFO. It stores the first two 1-bit ECC errors. The DDRSS_ECC_1B_ERR_ADR_LOG_REG register shows the address on top of the internal FIFO. Software should write 0x1 to the DDRSS_ECC_1B_ERR_ADR_LOG_REG[29-0] ECC_1B_ERR_ADR field to pop the FIFO and display the next address stored. The FIFO is loaded with the address for the next 1-bit ECC error if it is not full. No address comparison will be performed, that is, if a single address is associated with more than one ECC error, that address is logged twice.

The number of 1-bit ECC errors can be counted using the DDRSS_ECC_1B_ERR_CNT_REG register. The bridge also supports programming a threshold in the DDRSS_ECC_1B_ERR_THRSH_REG register. When the 1-bit error count is equal to or greater than the programmed threshold, the bridge sets the DDRSS_V2A_INT_RAW_REG[3] ECC1BERR bit and also triggers the DDR0_DDRSS_DRAM_ECC_CORR_ERR_LVL_0 interrupt. When servicing the interrupt, software needs to clear the error count otherwise further interrupts will not be triggered. For 2-bit ECC errors, the bridge sets the DDRSS_V2A_INT_RAW_REG[4] ECC2BERR bit and also triggers the DDR0_DDRSS_DRAM_ECC_UNCORR_ERR_LVL_0 interrupt. The bridge does not correct the data for these uncorrectable errors. Along with generating the interrupt, the bridge also reports an error to the requesting initiatior and sends all zeros for the data. The bridge also logs the address location for the error in the DDRSS_ECC_2B_ERR_ADR_LOG_REG register.

The bridge sets the DDRSS_V2A_INT_RAW_REG[5] ECCM1BERR bit and triggers the DDR0_DDRSS_DRAM_ECC_UNCORR_ERR_LVL_0 interrupt whenever it receives multiple 1-bit errors in different data words of the same SDRAM burst. This is done because the probability of receiving multiple 1-bit errors in different data words of the same SDRAM burst is very low. If this occurs, the chances are that there were multi-bit errors in each data word. Therefore, for reliability, pessimistic approach is taken to report these as a fatal error. The threshold for the number of 1-bit errors that result in an uncorrected error, reporting can be set by writing to the DDRSS_ECC_CTRL_REG[11-8] COR_ECC_THRESH field. For reliability, the threshold is always kept at 0/1 meaning 1-bit error in 2 or more data words is reported as a 2-bit error. For debug, the threshold can be changed to a higher value. Note that since these are multiple 1-bit errors, the statistic logging is done in the DDRSS_ECC_1B_ERR_CNT_REG and DDRSS_ECC_1B_ERR_ADR_LOG_REG registers.

9.1.3.4 Address Alias Prevention

The VBUSM2ZXI bridge checks the VBUSM address received against the valid SDRAM address space programmed in the DDRSS_V2A_CTL_REG register. If the VBUSM address for an access falls outside the programmed range the bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[1] AERR bit and also triggers the DDR0_DDRSS_V2A_OTHER_ERR_LVL_0 interrupt. The address and the Route ID for the command caused error are logged in the DDRSS_V2A_AERR_LOG1_REG and DDRSS_V2A_AERR_LOG2_REG registers.

The bridge fragments all incoming transactions into 32-byte accesses aligned at a 32-byte boundary. Therefore, for commands greater than 32 bytes with an address error, each fragment will report an error. This can cause multiple interrupts to be reported if software clears the error interrupt for the first fragment while other fragments are being executed. The address log register will always log the address for the fragment which caused the last interrupt. The valid address range can be programmed using the DDRSS_V2A_CTL_REG[9-5] SDRAM_IDX and DDRSS_V2A_CTL_REG[4-0] REGION_IDX fields.

Table 9-3 summarizes the scenarios for determining valid address range and interrupt generation.

Copyright © 2024 Texas Instruments Incorporated

Table 9-3. REGION_IDX and SDRAM_IDX Scenarios

Condition	Description
REGION_IDX = SDRAM_IDX	DDR region size is equal to the connected SDRAM size. It is the SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX < SDRAM_IDX	DDR region size is less than the connected SDRAM size. It is SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX > SDRAM_IDX	DDR region size is greater than the connected SDRAM size. Address error is generated if the address received falls outside the connected SDRAM size.

A write access outside the programmed range is discarded. A write error associated status is sent back to the VBUSM interface.

A read access outside the programmed range is executed on the SDRAM interface as a normal read, but data will contain all zeroes before forwarding it to the VBUSM interface. A read error associated status is sent back to the VBUSM interface along with the read data containing all zeroes.

When inline ECC is enabled, the available SDRAM size is reduced by 1/9th of the size programmed in the SDRAM_IDX field. Therefore, the bridge reports an error if an access falls outside the reduced SDRAM size when inline ECC is enabled. The reduced SDRAM size limit applies to all accesses, both to the protected and non-protected ECC regions.

9.1.3.5 AXI Bus Timeout

The VBUSM2AXI bridge has a timeout counter that expires when no AXI transaction can be sent to the DDR controller or no AXI response is received from the controller for a programmed time interval. The counter only counts when there are pending commands in the bridge and the AXI bus is idle. Therefore, the bridge will not time out during low-power modes. The time interval can be programmed by writing to the DDRSS_V2A_BUS_TO[23-0] BUS_TIMER field.

Upon the expiry of the counter, the bridge terminates all pending commands in its internal FIFOs, returns error responses, sets the DDRSS_V2A_INT_RAW_REG[2] TOERR bit and triggers the DDR0_DDRSS_V2A_OTHER_ERR_LVL_0 interrupt.

After a timeout occurs, the bridge terminates any new commands received and returns error response. Writing a value of 0x0 to the DDRSS_V2A_BUS_TO[23-0] BUS_TIMER field exits the timeout mode. The other method to exit the timeout mode is to reset the DDRSS0, thus resetting the VBUSM2ZXI bridge, the DDR controller, and the DDR PHY.

9.1.3.6 DDRSS Interrupts

The VBUSM2AXI bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[1] AERR bit, if the VBUSM address for an access that falls outside the DDR space programmed in the DDRSS_V2A_CTL_REG register.

The VBUSM2AXI bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[2] TOERR bit, if it detects a hang on its interface to the DDR controller.

The VBUSM2AXI bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[3] ECC1BERR bit, if the threshold for 1-bit ECC errors is met.

The VBUSM2AXI bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[4] ECC2BERR bit, in case of 2-bit errors for a read access performed within the SDRAM address range protected by ECC.

The DDRSS0 asserts particular interrupt line only if the interrupts are enabled by writing 0x1 to the corresponding bit in the DDRSS_V2A_INT_SET_REG register. The interrupts can be disabled by writing 0x1 to the corresponding bit in the DDRSS_V2A_INT_CLR_REG register.

When interrupts are enabled, the corresponding bits in the DDRSS_V2A_INT_STAT_REG register are also set if an interrupt condition occurs. The interrupts can be cleared once serviced by writing 0x1 to the corresponding bit in the DDRSS_V2A_INT_STAT_REG register as well as writing to the DDRSS_V2A_EOI_REG register.

Copyright © 2024 Texas Instruments Incorporated

The subsystem will send an interrupt pulse, if there are any bits set in the Interrupt Status register (DDRSS_V2A_INT_STAT_REG) when the End of Interrupt register (DDRSS_V2A_EOI_REG) is written.

VBUSM2AXI Bridge Events shows the events that are generated by the VBUSM2AXI bridge.

Table 9-4. VBUSM2AXI Bridge Events

Event Flag	Event Mask	Description
DDRSS_V2A_INT_RAW_REG[4] ECC2BERR DDRSS_V2A_INT_STAT_REG[4] ECC2BERR	DDRSS_V2A_INT_SET_REG[4] ECC2BERR_EN DDRSS_V2A_INT_CLR_REG[4] ECC2BERR_EN	Generated in case of 2-bit errors for a read access within the ECC protected SDRAM address range. For more information, see Section 9.1.3.3.3.
DDRSS_V2A_INT_RAW_REG[3] ECC1BERR DDRSS_V2A_INT_STAT_REG[3] ECC1BERR	DDRSS_V2A_INT_SET_REG[3] ECC1BERR_EN DDRSS_V2A_INT_CLR_REG[3] ECC1BERR_EN	Generated in case of meeting the threshold for 1-bit ECC errors. For more information, see Section 9.1.3.3.3.
DDRSS_V2A_INT_RAW_REG[2] TOERR DDRSS_V2A_INT_STAT_REG[2] TOERR	DDRSS_V2A_INT_SET_REG[2] TOERR_EN DDRSS_V2A_INT_CLR_REG[2] TOERR_EN	Generated in case of a hang of the interface between the bridge and the DDR controller. For more information, see Section 9.1.3.5.
DDRSS_V2A_INT_RAW_REG[1] AERR DDRSS_V2A_INT_STAT_REG[1] AERR	DDRSS_V2A_INT_SET_REG[1] AERR_EN DDRSS_V2A_INT_CLR_REG[1] AERR_EN	Generated if the VBUSM address for an access falls outside the programmed range. For more information, see Section 9.1.3.4.

9.1.3.7 DDRSS Memory Regions

Table 9-5 shows all memory regions associated with the DDRSS0.

Table 9-5. DDRSS0 Memory Regions

Region	Start Address	End Address	Region Size
DDRSS0 wrapper logic registers	0x00F300000	0x00F3001FF	512 B
DDR controller registers	0x00F308000	0x00F309FFF	8 KB
DDR PHY independent module registers	0x00F30A000	0x00F30BFFF	8 KB
DDR PHY registers	0x00F30C000	0x00F30FFFF	16 KB
External SDRAM data space	0x080000000	0x0FFFFFFFF	2 GB
	0x880000000	0x9FFFFFFFF	6 GB

9.1.3.8 DDRSS Dynamic Frequency Change Interface

This interface is used for handshaking between DDRSS0 and CTRL_MMR0 to dynamically change DDR clock frequency to support LPDDR4 Frequency Set Point (FSP). The frequency change can be initiated either by a SoC processor or by the DDRSS0.

The associated CTRL_MMR0 registers for processor initiated frequency change are:

- CTRLMMR_CHNG_DDR4_FSP_REQ
- CTRLMMR_CHNG_DDR4_FSP_ACK

The associated CTRL_MMR0 registers for DDRSS0 initiated frequency change are:

- CTRLMMR_DDR4_FSP_CLKCHNG_REQ
- CTRLMMR_DDR4_FSP_CLKCHNG_ACK

The sequence for an SoC processor initiated frequency change is as follows:

1. The processor writes the desired frequency to the CTRLMMR_CHNG_DDR4_FSP_REQ[1-0] REQ_TYPE field.

Copyright © 2024 Texas Instruments Incorporated

2. The processor sets to 0x1 the CTRLMMR_CHNG_DDR4_FSP_REQ[8] REQ bit to initiate frequency change.
3. The processor programs PLL12 according to the CTRLMMR_CHNG_DDR4_FSP_REQ[1-0] REQ_TYPE value.
4. The processor polls the CTRLMMR_CHNG_DDR4_FSP_ACK[7] ACK and CTRLMMR_CHNG_DDR4_FSP_ACK[0] ERROR bits to check if the frequency change has been completed successfully.

The sequence for DDRSS0 initiated frequency change is as follows:

1. DDRSS0 requests frequency change by asserting the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[7] REQ bit and the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[1-0] REQ_TYPE field. The REQ bit is also connected to the DDR0_DDRSS_PLL_FREQ_CHANGE_REQ_0 interrupt.
2. Software reads the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[1-0] REQ_TYPE value and programs PLL12 accordingly.
3. After the DDRSS0_FCLK has been changed software should set to 0x1 the CTRLMMR_DDR4_FSP_CLKCHNG_ACK[0] ACK bit.

9.1.3.9.1 DDR PHY Interface (DFI)

The DDR controller and DDR PHY are connected via DDR PHY Interface (DFI) which is used for transferring control information and data between the PHY and the controller. For more information about DFI, see http://www.ddr-phy.org/.

Copyright © 2024 Texas Instruments Incorporated

9.1.3.9.2 Command Queue

The DDR controller contains a command queue which uses a placement algorithm to determine the order of commands to be placed into the command queue. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at a time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. The placement logic also attempts to maximize efficiency of the DDR controller through command grouping and bank splitting.

9.1.3.9.2.1 Placement Logic

The placement logic is a 2-stage queue which determines the order of commands that run in the DDR controller. The placement logic follows rules for determining placement of new commands into the queue, relative to the contents of the command queue at that time. Placement is determined by considering coherency, address collisions, source collisions, data collisions, user assigned priority, latency, age, and command type to offer low latency for critical controllers while optimizing bandwidth for all controllers. A second reordering stage allows ready-to-run commands to start even if the head-of-queue command is not yet ready to run. In addition, the queue can be disabled completely, resulting in an in-line queue that services requests in the order that they arrive.

The DDR controller also has a full look-ahead facility that reduces the effect of page misses by pre-conditioning rows for upcoming requests by using “spare” cycles in preceding transactions.

9.1.3.9.2.2 Command Selection Logic

After a command is in the command queue, command selection logic determines the method of pulling commands from the queue for running. On each clock cycle, the selection logic scans the entries of the command queue for determining the command to run. Commands for running are based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing, and conflicts. Similar to the placement rules, a command does not run before a command that was placed ahead of it in the command queue if it conflicts with address, source ID, or bank commands. Lower priority commands can run ahead of higher priority commands if the higher priority commands are not ready to run, as long as they do not conflict with commands that are ahead in the command queue.

9.1.3.9.3 Transaction Processing

The transaction command processing logic is used to process the commands in the command queue. The logic organizes the commands to the memories in such a way that data throughput is maximized. Bank opening and closing cycles are used for data transfers. The logic reviews the entire command queue for look-ahead of which banks have to be accessed in the future and ensures that the programed memory timing conditions are met. This flexibility allows the controller to be tuned to extract the maximum performance out of memories. During processing, the controller examines the commands and issues the appropriate set of signals to the memory.

9.1.3.9.4 Paging Policy

The DDR controller offers a flexible paging policy that allows open page operation, closed page operation, or an auto-precharge-per-command option that allows both modes simultaneously. Auto-precharge-per-command allows marking a particular controller or transaction (for example, a CPU cache) as a closed-page transaction. This type of transaction reduces power and improves latency for the next transaction to a different row in the same SDRAM bank. Other transactions can be marked as open page transactions. This type of transaction reduces power and improves latency and bandwidth to the next transaction to the same row in the same SDRAM bank.

9.1.3.9.5 DDR Controller Initialization

Once the power to the SDRAM and SoC is stable, the DDR controller must be initialized. It then automatically initializes the external memory. Please refer to the Processor SDK for the software drivers to initalize the DDR registers and memory

9.2 Region-based Address Translation (RAT) Module

This section describes the RAT functionality.

9.2.1 RAT Functional Description

9.2.1.1 RAT Availability

lists the device modules and subsystems which have RAT module.

9.2.1.2 RAT Operation

The RAT module performs a region based address translation. It translates a 32-bit input address into a 48-bit output address. Any input transaction that starts inside of a programmed region will have its address translated, if the region is enabled. Any disabled region is ignored from the translation lookup.

RAT has 16 regions, with each region having dedicated registers that define its attributes:

- Base address of the region, via the RAT_BASE_k register.
- Size of the region, via the RAT_CTRL_k register.
- Translated base address (48-bit). It is defined by 32-bit lower address via the RAT_TRANS_L_k register, and 16-bit upper address via the RAT_TRANS_U_k register.

The input addresses are compared against all the enabled regions in parallel. The region size defines how many of the lowest address bits are included in the region space, starting from a 1B space to a 4GB space. Then the upper bits not part of the region are used for the lookup and comparison, matching those bits of the input addresses against the region base address. The region matches when it is enabled and the compare matches. The first region that matches has the output address set with the region translated base address upper bits. The lower bits that are part of the region size are copied from the input address to the output address. If there are no region matches then the input address is copied to the output address entirely.

RAT does not automatically correct transactions that cross region boundaries, that is, start inside of a region and end outside of it, or start outside of a region and end inside of it. If a boundary crossing transaction is detected, then RAT annuls the transaction as illegal, generates an interrupt and logs an error, as explained in *RAT Error Logging*.

Note

The region base address and translated base address must be aligned to the defined region size. For example, if the defined region size is 64KB, then the two addresses must be 64KB aligned. This is software responsibility as RAT does not perform such alignment check. Regions that are not aligned have unpredictable results.

Moreover, multiple region definitions must not overlap in their covered address space. RAT does not check for this, so it is software responsibility to take care of it. Overlapping regions may lead to unpredictable results.

9.2.1.3 RAT Error Logging

The error log consists of a series of registers that capture the details of the transaction, including the input address that caused the error. These registers are the following:

- RAT_EXCEPTION_LOGGING_HEADER0 and RAT_EXCEPTION_LOGGING_HEADER1
- RAT_EXCEPTION_LOGGING_DATA0 through RAT_EXCEPTION_LOGGING_DATA3

The RAT module can capture one error before it is cleared by software. The error logging is enabled by default, but can be disabled via the RAT_EXCEPTION_LOGGING_CONTROL[0] DISABLE_F bit. Upon error logging an interrupt is also generated. To clear the log, software must either read the final error logging register, or manually clear the RAT_EXCEPTION_PEND_CLEAR[0] PEND_CLR bit by setting it to 0x1. This will clear the error status, and not the actual log registers, but it does allow the next error to be captured into the log registers. If the status is not cleared and additional errors are detected, they are not logged.

Copyright © 2024 Texas Instruments Incorporated

After an error occurs and is cleared (whether by reading the final error logging register or by clearing the status bit), the RAT_EOI_REG register must be written to guarantee the next interrupt pulse will be produced.

shows the RAT source ID mapping which is associated with the RAT_EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID field.

Chapter 10

Interrupts

This chapter describes the details related to device interrupts.

10.1 Interrupt Architecture.....820

Copyright © 2024 Texas Instruments Incorporated

10.1 Interrupt Architecture

AM62 Interrupt Architecture includes information on how to utilize various interrupts and events in the system and relationships between interrupts and events.

An interrupt is defined as a physical signal which can be routed to the interrupt controller of various processors, which can cause the Interrupt Service Routing (ISR). This physical signal can be either a pulse or level and the polarity can be either negative or positive. And an interrupt is correspondent to an individual wire.

An event is defined as information transported by the event bus or PSI_L bus. Events are coded using an event index. The same event bus or PSI_L bus is used to transport multiple events. An event can also be routed and multiplexed to different locations. Events can't trigger a processor's ISR directly. It has to go through the Interrupt Aggregator (IA) to convert the event into an interrupt line. For more information, see Interrupt Aggregator (INTAGGR) *, Interrupt Aggregator (INTAGGR)*

The DMA transfer using BCDMA and PktDMA in AM62 can only be triggered using an event. The SoC level interrupt could be used as a BCDMA trigger using L2G logic. Interrupts in the SoC level can't be used to trigger a pktDMA transfer.

Each type of the processor has its unique interrupt controller. All A53 cores share a single Generic Interrupt Controller (GIC). Each M4F micro controller has its own dedicated interrupt controller, called Nested Vector Interrupt Controller (NVIC). Each R5 micro controller has its own dedicated interrupt controller, called Vectored Interrupt Manager (VIM). ICSSM uses an embedded local interrupt controller called INTC to manage its interrupts, refer to Table 10-1. Please refer to the following sections for the detailed usage of GICSS, VIM, INTC and MCUSS NVIC.

Table 10-1. Interrupt Controllers

Processors	Interrupt Controllers
A53 core 0	All four A53 cores share the same GICSS
A53 core 1	
A53 core 2	
A53 core 3	
R5 core inside R5FSS	Dedicated VIM inside R5FSS
M4F core inside MCUSS	Dedicated NVIC inside MCUSS
TIFS	Dedicated NVIC for TIFS
HSM	Dedicated NVIC for HSM. HSM receives the same sets of interrupt as TIFS
ICSSM	INTC embedded inside ICSSM

AM62 also contains multiple SoC level interrupt routers. The main function of those SoC level interrupt routers is to provide flexibility to select interrupt sources from a large group of interrupt sources. There are multiple places which utilize this feature, such as GPIO interrupts and some time synchronization related interrupts.

AM62 contains two ESM modules. ESM is used to consolidate/monitor the error events in the device. In this document, ESM may also be referred to as ESM0.

AM62 also has some chip level glue logic to convert some miscellaneous signals used as interrupt sources. Those miscellaneous signals are normally self-clear signals and do not need to clear after the Interrupt Service Routing (ISP) like the normal interrupts generated by the peripherals.

Figure 10-1 shows the high level interrupt architecture in AM62.

Copyright © 2024 Texas Instruments Incorporated

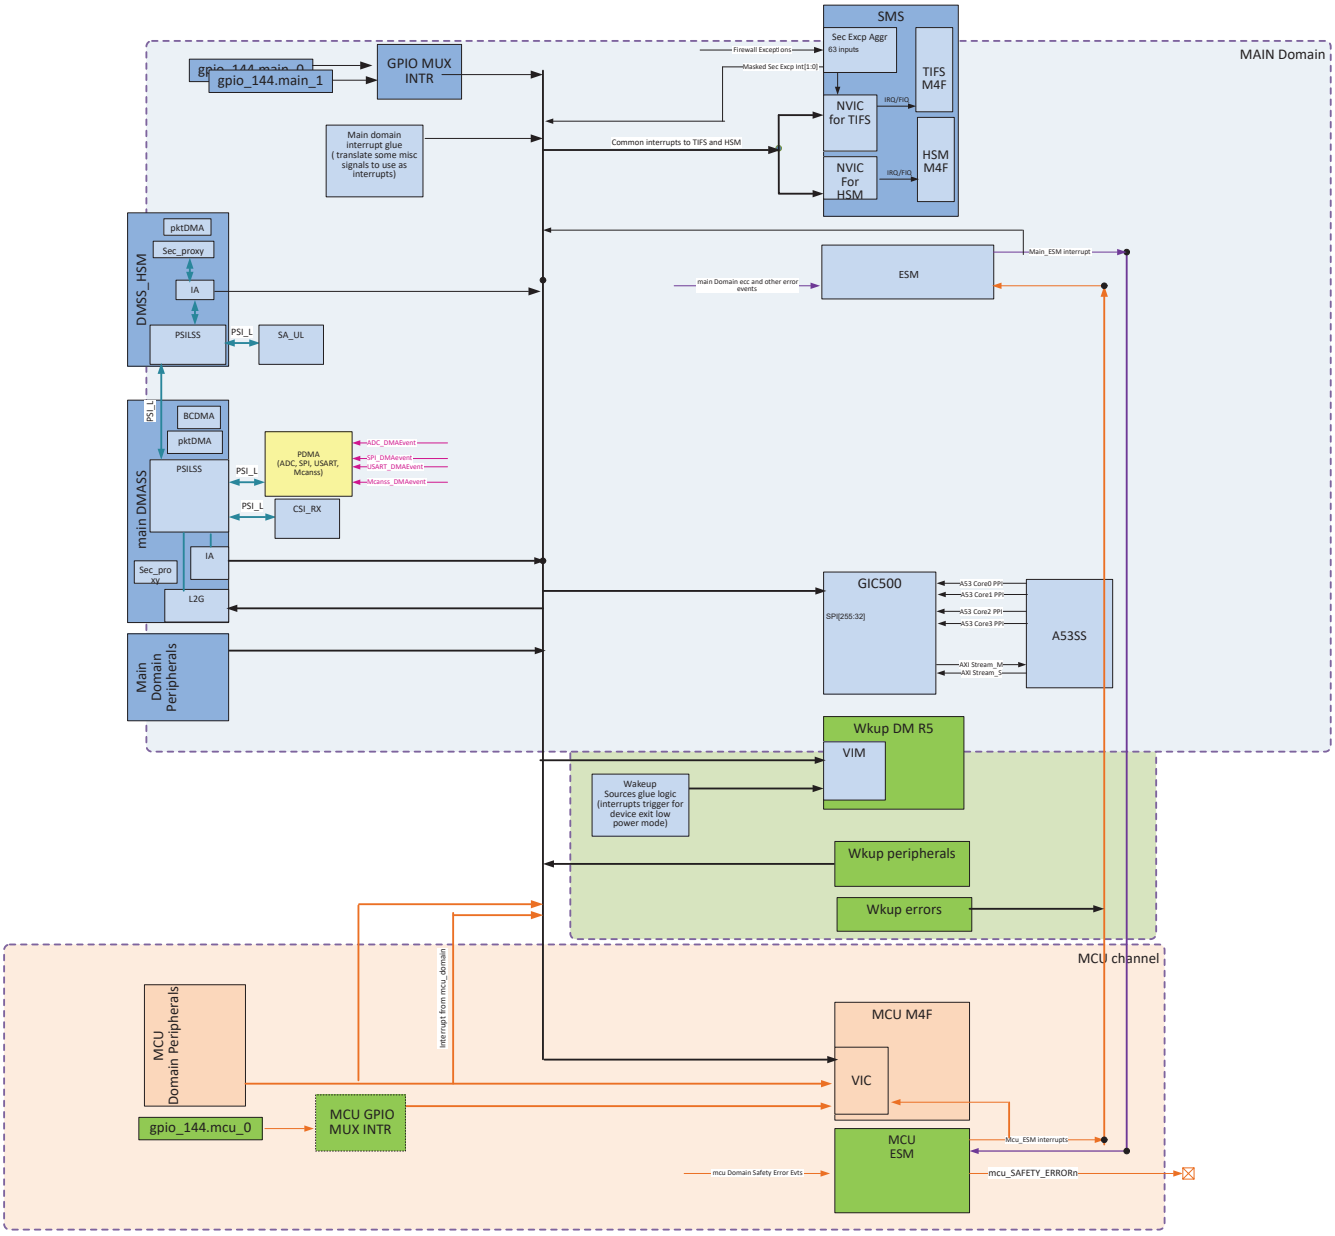

Figure 10-1. AM62 Interrupt Architecture

10.1.1 ESM Connectivity

AM62 contains two ESM modules to consolidate the error interrupts in SoC. One is in the Main domain and one is in the MCU domain. Figure 10-2 shows how error interrupts are connected to these two ESM.

Copyright © 2024 Texas Instruments Incorporated

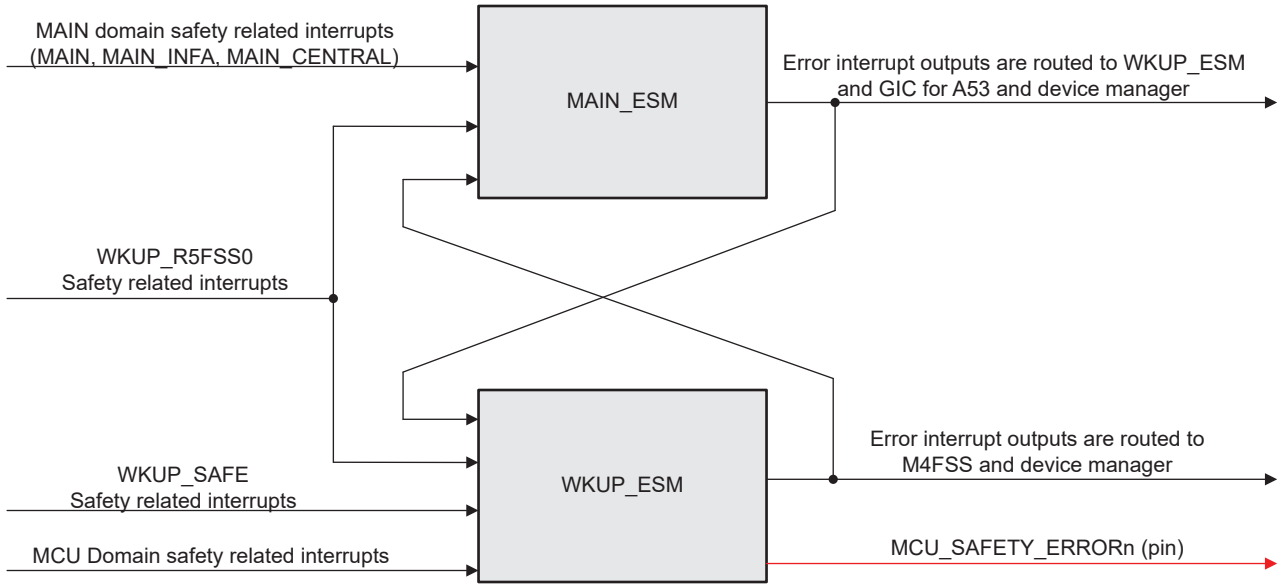

Figure 10-2. ESM Connection

The error interrupts from the Wkup_DM domain are routed to both Main ESM and MCU ESM. Users can configure ESM to cause ESM generating interrupt output from the interrupt inputs. The interrupt outputs of the Main ESM are routed as interrupt inputs to the MCU ESM. The interrupt outputs of the MCU ESM are routed as the interrupt inputs to the Main ESM. This means that user can configure the device to use one ESM to monitor the error interrupts for the whole device. AM62 supports the following three use cases.

10.1.1.1 Using MCU ESM to Monitor All Error Events in SoC

In this use case, the Main ESM is used to consolidate all the error interrupts in the Main domain and Wkup_DM domain as main ESM's interrupt outputs, which are routed as interrupt inputs to the MCU ESM.

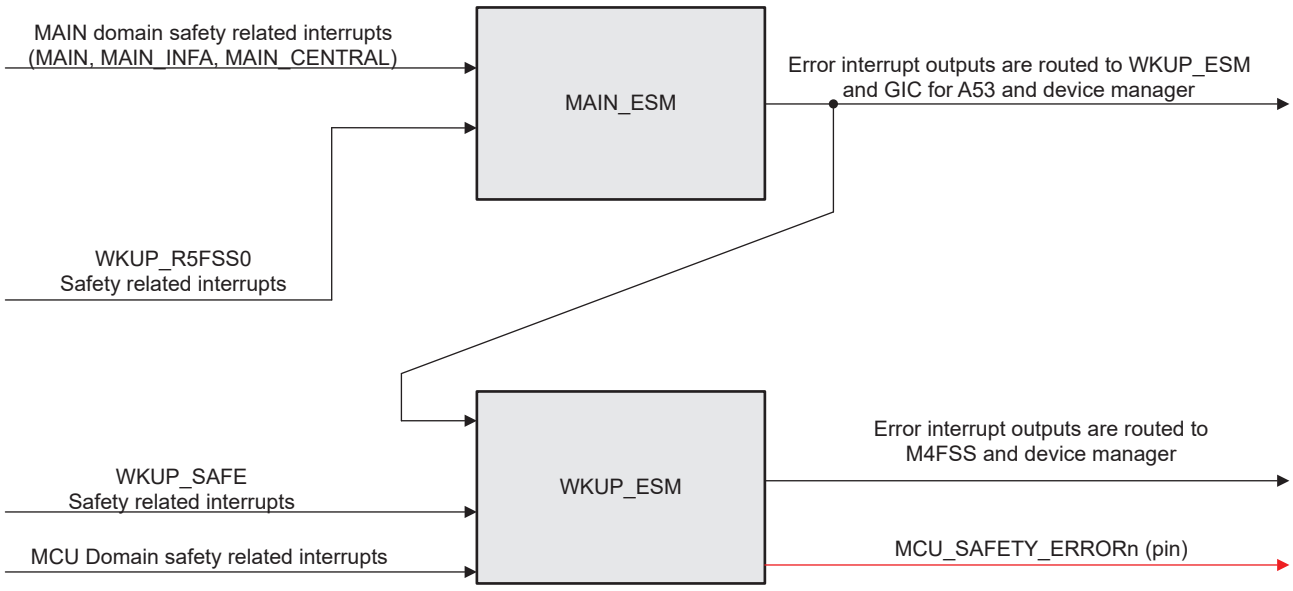

Figure 10-3. Using MCU ESM for All Error Interrupts in SoC

In this use case, the Main ESM should be configured to disable the interrupt inputs coming from the MCU ESM interrupts. If those interrupt inputs are not disabled by the Main ESM, the dependence loop will be formed as following:

Copyright © 2024 Texas Instruments Incorporated

1. Error interrupts in the Main domain are routed to Main ESM triggers interrupt outputs generated by the Main ESM
2. The error interrupt outputs from the Main ESM are routed to the MCU ESM as interrupt inputs
3. Those error interrupt inputs triggers the MCU ESM generating its error interrupts outputs
4. Those interrupt outputs from the MCU ESM are routed back to the Main ESM as interrupt inputs. If those interrupts are not disabled at the Main ESM, it will trigger Main ESM generating interrupt outputs in the Main ESM again. Going back to step 1 again.

In addition, since Wkup_DM error events are already routed to the Main ESM, so the input events in the MCU ESM connecting to those error events from the Wkup_DM domain shall be disabled, otherwise those events can trigger the interrupt in both the Main ESM as well as the MCU ESM

10.1.1.2 Using MAIN ESM to Monitor All Error Interrupts in SoC

In this configuration, the MCU ESM is used to consolidate all the error interrupts from the MCU domain and the Wkup_safe domain as interrupt outputs, and those interrupt outputs from the MCU ESM are routed as interrupt inputs to the Main ESM. In order to avoid the interrupt dependence loop, the MCU ESM shall disable the interrupt inputs from ESM0.

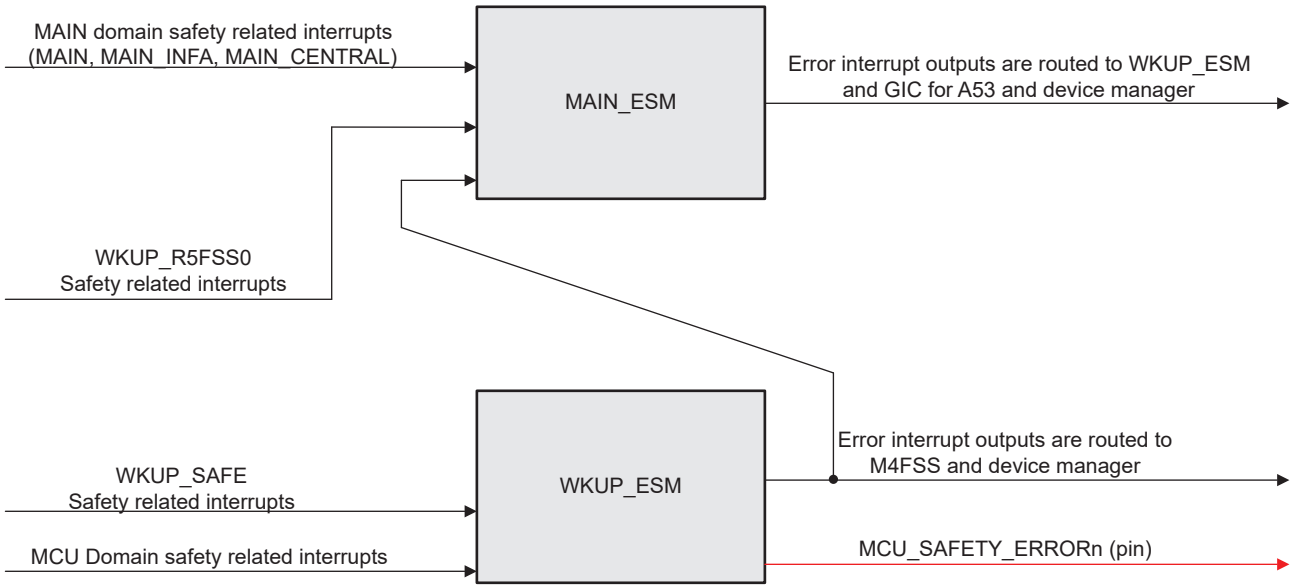

Figure 10-4. Using MAIN ESM to Monitor All Error Interrupts in SoC

10.1.1.3 ESM Configuration During Deep Sleep Mode

When device is in deep sleep mode, only the components in the Wkup_DM domain and the Wkup_safe are available. The Main domain is powered off, so the Main ESM is no longer available. Since MCU ESM is located in the Wkup_safe domain, the MCU ESM is monitoring all of the error events during the deep sleep mode and informs the device manager.

10.1.2 Events

Events are mainly generated by the BCDMA and the pktDMA. In addition, the sec_proxy IPC module also generates event outputs. Events can be directly utilized by the BCDMA and the pktDMA. If those events need

Copyright © 2024 Texas Instruments Incorporated

to be processed by processor, the events need to be converted to interrupts through the Interrupt Aggregator (IA) Module. Refer to for information on how IA is used. Figure 10-6 shows which modules generates events and how the events are converted to the interrupt.

BCDMA transfer can only be triggered through an event or by software. There are 32 SoC level interrupt signals that can be used to trigger a BCDMA transfer. Figure 10-7 shows all of the possible interrupts and signals that can be used to trigger BCDMA transfer autonomously.

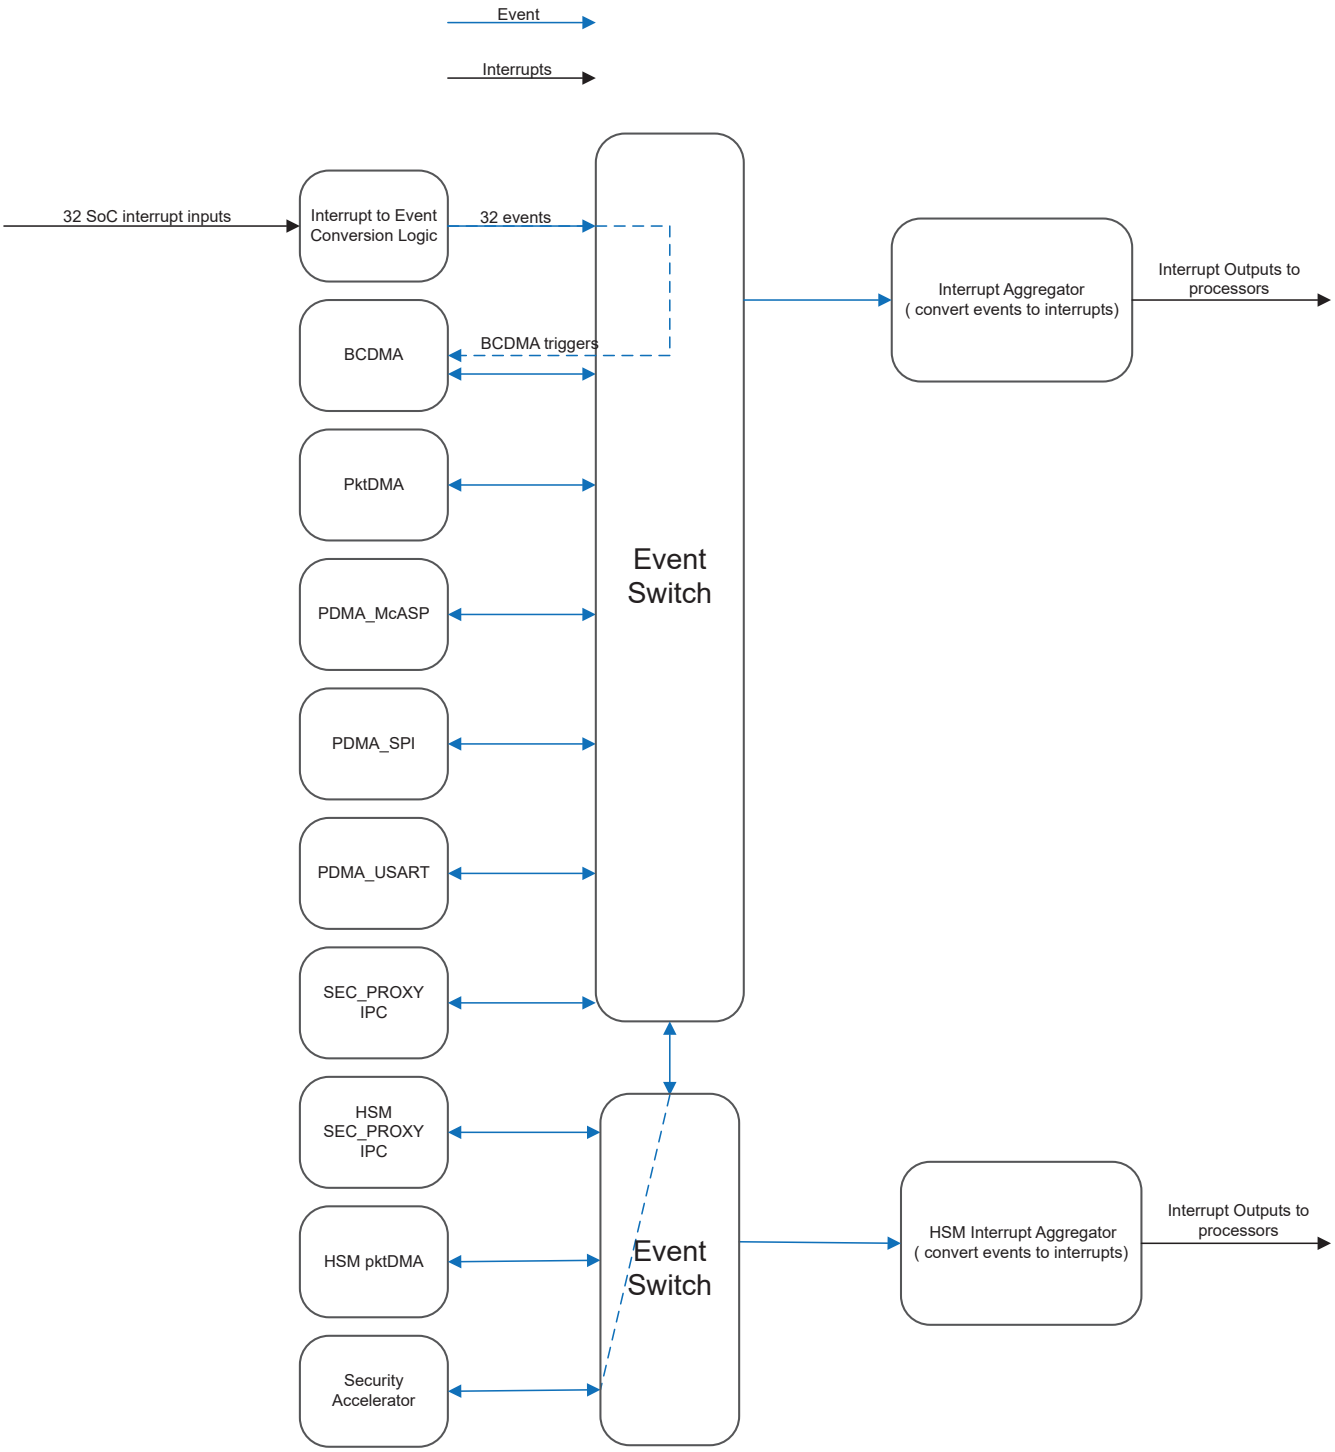

Figure 10-6. Event Handling

10.1.3 Interrupt Router (INTROUTER)

10.1.4 Time Synchronization Support

Time sync event router enables the flexibility to choose any time synchronization source, whether it is the time synchronization source coming from the external pin or the synchronization pulse generated by the internal peripheral or from the ARM system time counter. Time sync event router also enables the system to utilize time synchronized signal as block copy DMA trigger or as periodical control of EPWM.

The compare event router allows the processor to be interrupted by any of the compared events periodically or use a compared event to generate periodical control on EPWM or triggering block copy DMA transfer. Figure 10-8 shows all the synchronization sources and compare events in the device.

10.1.5 GPIO Interrupt Handling

There are three GPIO modules in the device, which could generate almost 200 interrupts. Those GPIO interrupt outputs are routed to the GPIO interrupt router first before they are routed to the final interrupt destination. The GPIO interrupt router allows each output to select each GPIO interrupt independently.

Two of the GPIO modules in the Main domain use one GPIO interrupt router while the GPIO module in MCU domain has its own dedicated GPIO router. See Figure 10-9.

10.1.6 Utilizing Miscellaneous Signals as Interrupt

Some of the signals are aggregated through glue logic and need to be handled separately.

10.1.6.1 Aggregated Interrupt from Timeout Gasket

There are multiple timeout gaskets in SoC, some of them are inserted at the initiator side and the others are inserted at the target interface side. Each timeout gasket module generates its own interrupt. Instead of routing the interrupt from each timeout gasket individually to the processor, the interrupts from all the timeout gasket inserted at the target sides are aggregated together (ORed), and all the interrupts from all the timeout gasket inserted at the initiator sides are aggregated together (ORed). The status of each interrupt status is captured by the TOG_STAT registers in both wkup_ctrl_mmr and mcu_ctrl_mmr. Refer to Figure 10-10.

Copyright © 2024 Texas Instruments Incorporated

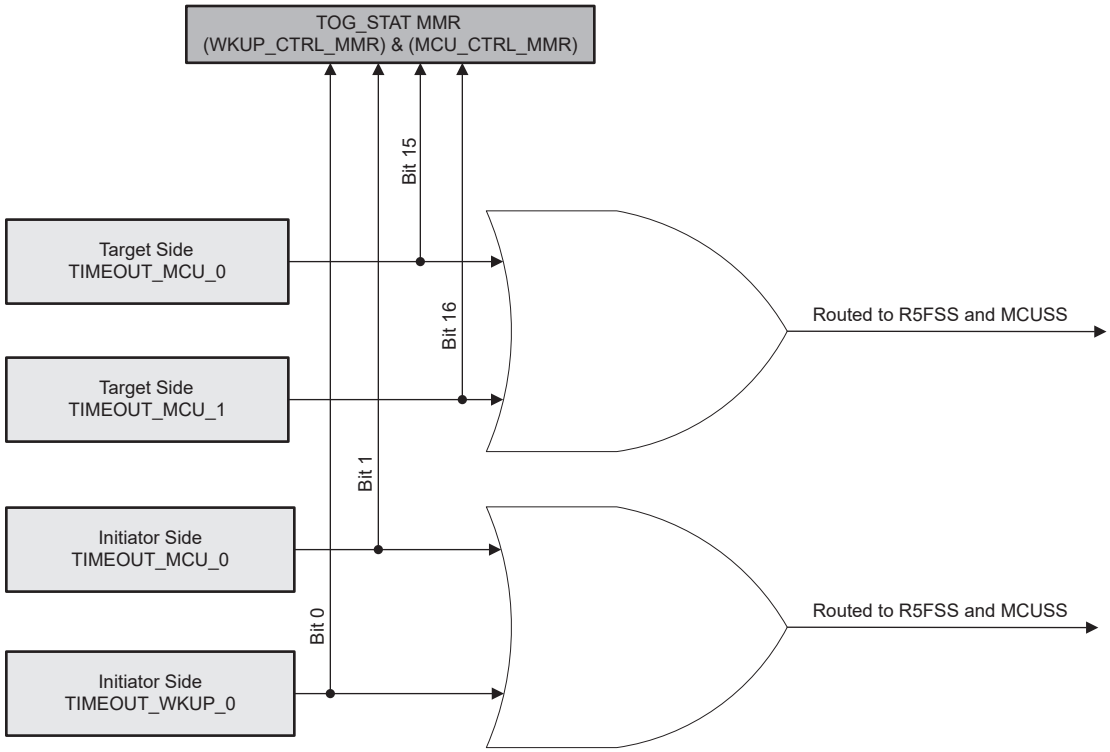

Figure 10-10. Interrupt from Timeout Gaskets

10.1.6.2 Aggregated DCC Interrupt

There are multiple DCC modules in the main domain and each DCC module generates its own DCC_done interrupt. The DCC_done interrupt from all the DCC modules in the main domain are aggregated (ORed) together before it is routed to all the processors, refer to Figure 10-11.

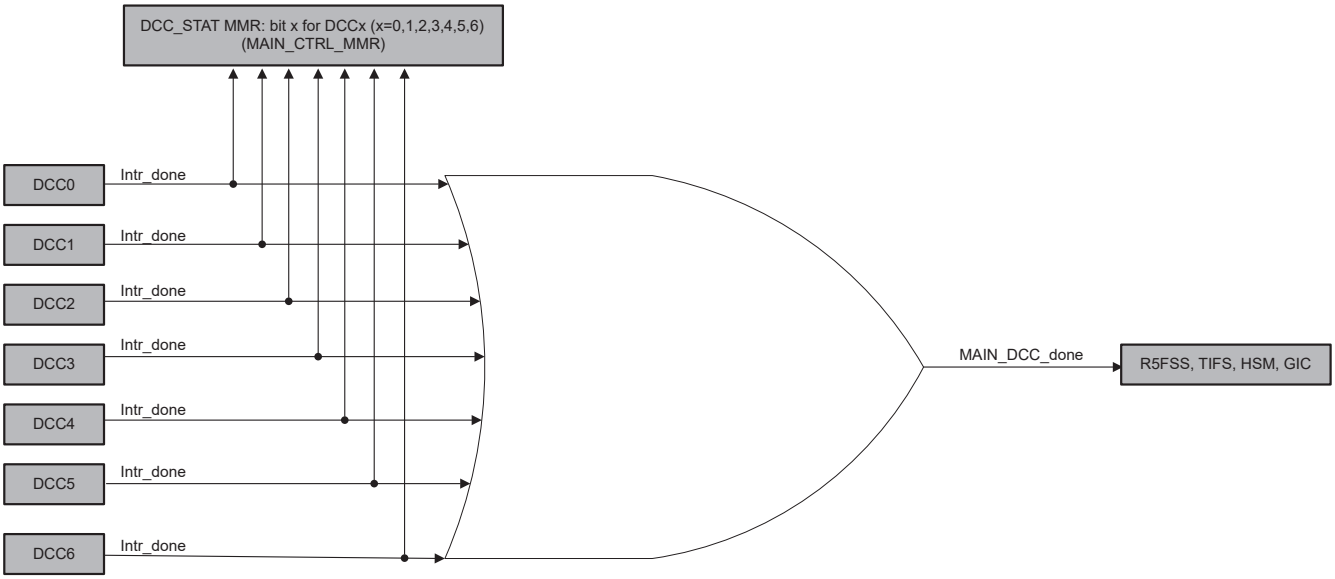

Figure 10-11. DCC Intr_done Interrupt Aggregation

Copyright © 2024 Texas Instruments Incorporated

10.1.6.3 Aggregated Access Error Interrupt from CBASS

CBASS modules are the interconnection blocks on the SoC level to provide access path between initiators and targets. When the transaction is not completed successfully, an interrupt is generated by the CBASS and the error transaction is logged by the CBASS module.

There are multiple CBASS modules on the SoC level to provide three layers of interconnect: the data plane, security configuration plane and debug configuration plane. The CBASS access error from the security configuration plane is only routed to TIFS and HSM, and the other CBASS access errors are aggregated before routing it to the processors, refer to Figure 10-12.

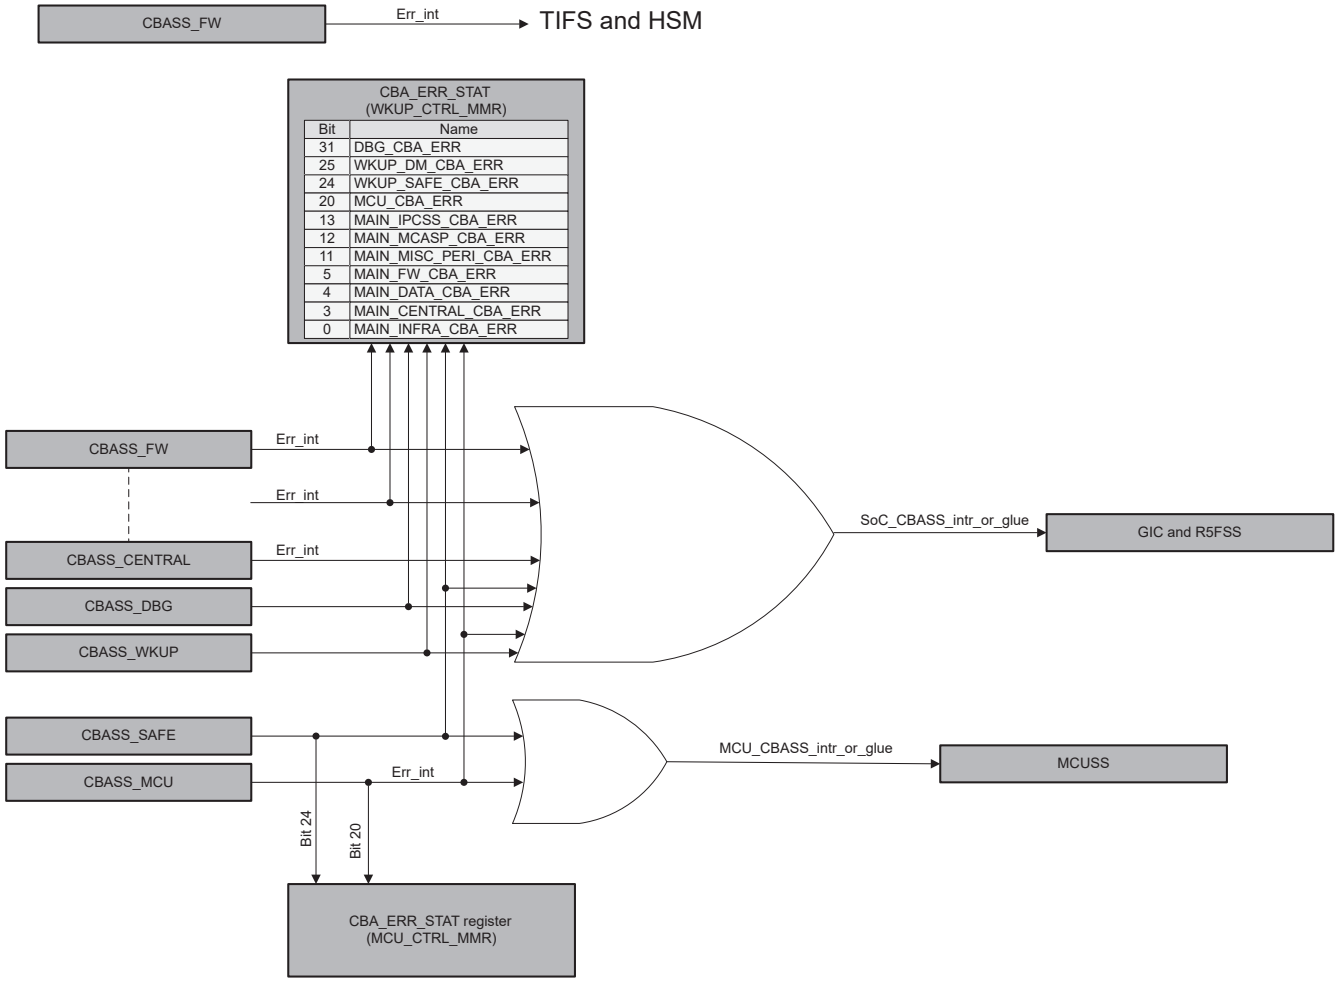

Figure 10-12. Aggregated CBASS Access Error

10.1.6.4 Access Error to Control Register Block Interrupt Aggregation

There are multiple register blocks on the SoC level, and each register block generates an error interrupt when there is an access error. Those access error interrupts are aggregated together before they are routed to processor, refer to Figure 10-13.

Chapter 11

Data Movement Architecture

This chapter describes the data movement architecture of the device.

11.1 Data Movement Architecture Overview 867
11.2 Data Movement Subsystem (DMSS) 928
11.3 Peripheral DMA (PDMA) 958

Copyright © 2024 Texas Instruments Incorporated

11.1 Data Movement Architecture Overview

This chapter is a high-level summary of the data movement architecture implemented in the device.

11.1.1 Overview

The primary goal of the device Data Movement Architecture and related Subsystems is to ensure that data can be efficiently transferred from a producer to a consumer while meeting the real time requirements of the system can be met.

The Data Movement Subsystem (DMSS) aims to facilitate direct memory access (DMA) and provides a consistent Application Programming Interface (API) to the host software.

Data movement tasks are commonly offloaded from the host processor to peripheral hardware to increase system performance. Significant performance gains may result from careful design of the interface between the host software and the underlying acceleration hardware. In networking applications, packet transmission and reception are critical tasks. In general purpose compute, ping pong buffer prefetch and store are critical tasks as well as general mis-aligned block copy operations.

The design goals for the device Data Movement Architecture and are as follows:

- Minimize cost
- Minimize host overhead
- Maximize memory use efficiency
- Maximize bus burst efficiency
- Maximize symmetry between transmit/receive operations
- Maximize scalability for number of connections / buffer sizes / queue sizes / protocols supported
- Minimize protocol specific features
- Minimize complexity

11.1.1.1 Ring Accelerator (RINGACC)

The ring accelerator (RINGACC or RA) is a hardware module that is responsible for accelerating management of various types of queues in the system. The RINGACC accelerates passing of packets between a producer and consumer in normal system memory (including cached memory). The RINGACC is capable of accelerating the read/write pointer maintenance and occupancy tracking operations.

The ring accelerator operates like a bus infrastructure bridge in that it passes transactions through it between a source and destination interface. As transactions are passed, the RINGACC modifies the address, byte count, and transaction identifiers and internally updates the occupancies/pointers.

Each queue that the RINGACC provides can operate in either exposed-ring-mode or private-queue-mode.

- The exposed ring mode allows software to directly access the underlying ring structure to add or remove items from the tail or head of the ring respectively. Whenever items are added or removed from a ring, the host software is required to write to a corresponding doorbell register (RINGRT[a]_RT_DB) to increment or decrement the ring occupancy. When using the exposed ring mode, no proxy is required between the software and the RINGACC but all queue add operations require a memory fence to be performed to ensure that the data has landed in a snoopable cache before the doorbell register is written.
- The private queue mode provides an abstract view of the ring so that the host software does not need to know the actual physical address location or current read or write indexes of the ring. The private queue mode provides a memory window for each ring which when written redirects the write to the address pointed to by the write pointer and when read redirects the read to the address pointed to by the read pointer. The same address range is always used to push or pop elements from a given queue.

Rings are an implementation of a logical queue with the following limitations:

- Each ring has a finite size. When rings are used in exposed ring mode the following conditions apply:
  - A separate operation is required to write/read the contents of a ring and to update the occupancy of the ring

Copyright © 2024 Texas Instruments Incorporated

- It is not straightforward to allow multiple producers to write to a ring or multiple consumers to read from a ring. Additional synchronization and pointer passing is required since rings require software to manage one of the pointers for the queue.
- An exposed ring cannot be used when software or hardware needs to both read and write the same queue (such as for a DMA RX free queue where errors can have the DMA write the element back onto the same RX free queue). Since software owns one side of the pointers and hardware owns the other, they cannot be kept coherent if either side needs to update either at any time.

The RINGACC allows each ring to be configured to a different primary element size. Element sized chunks of data are placed onto and retrieved from rings when queuing or de-queueing occurs. Element sizes can be as small as 4 bytes or as large as 256 bytes.

11.1.1.2 Secure Proxy (SEC_PROXY)

A proxy provides a mechanism for software to access the RINGACC coherently when the processor does not support large bursts. The RINGACC requires a single burst for each operation so that it maintains atomicity and coherence by relying on the atomicity of the bursts on the bus interconnect fabric, since it only delivers a single burst to the RINGACC before the next. Since processors are usually limited in the size of a burst they can deliver natively, such as 32 to 128 bits, they cannot be used directly with the data access region of the RINGACC for larger element sizes. The proxy solves this gap by providing a temporary space for the software to form a larger burst of data before it is sent to the RINGACC. The proxy allows smaller processor accesses to the data and only forwards to the RINGACC when the entire data burst is complete, as directed by the software.

Each proxy hardware can support multiple threads of software (whether on the same or different processors) operating on bursts at the same time, and they do not interfere with each other, as long as each thread of software only operates on its thread in the proxy. Each proxy thread also supports access to any RINGACC queue via different offsets similar to how the RINGACC provides access to the queues via different offsets.

A special version of a proxy is the Secure Proxy that provides secured access to RINGACC queues for communication to the security initiator of the system. It provides basically the same function as a normal proxy. The data burst size is fixed for message sizes to the security initiator, so there is no support for all the element sizes of the RINGACC. The security initiator locks down the RINGACC queue to access and direction for each proxy thread so that the software cannot access anything they shouldn’t, so the software only sees a single queue (unlike the normal proxy), and any attempts to access another queue or access it in violation of how the security initiator defined and an error will be flagged. This allows for a much more controlled setup for passing messages to the security initiator.

11.1.1.3 Interrupt Aggregator (INTAGGR)

The interrupt aggregator (INTAGGR or INTA) is a hardware module which provides a persistent view of the real time status of various DMA components within the overall SoC DMA system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

The INTA block provides the following functions:

- Conversion of local event signal lines into global events
- Performing an 'Y-split' operation of global events
- Counting global events
- Steering and aggregation of global events into specified bit positions in one of N interrupt cause registers
- SoC interrupt-architecture-compliant set/clear and mask set/clear functionality to cover interrupt cause registers

11.1.1.4 Packet DMA (PKTDMA)

The PKTDMA module supports the transmission and reception of various packet types. The PKTDMA is architected to facilitate the segmentation and reassembly of DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows

Copyright © 2024 Texas Instruments Incorporated

packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

A block diagram of the PKTDMA Controller is shown below:

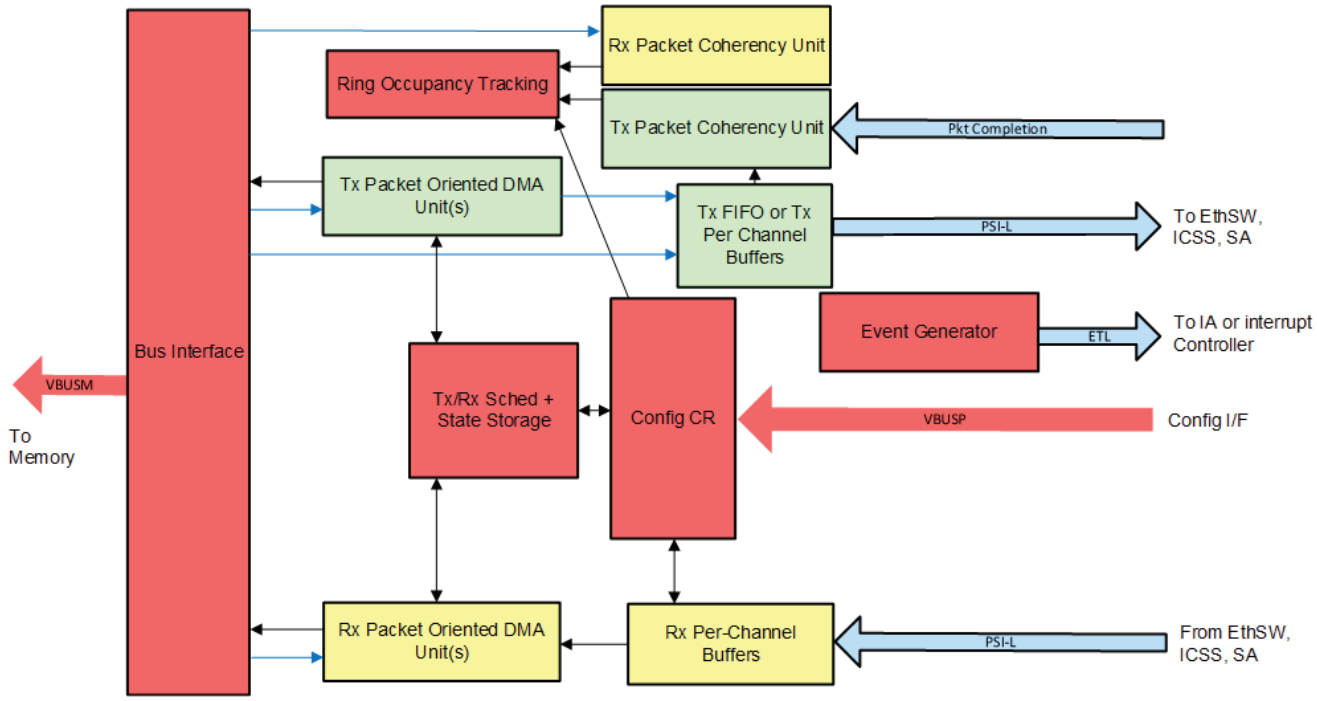

Figure 11-1. PKTDMA Block Diagram

11.1.1.4.1 PKTDMA Submodule Descriptions

11.1.1.4.1.1 Bus Interface Unit

The Bus Interface Unit is responsible for merging and buffering all of the transactions that originate from the various initiator blocks inside the DMA controller into the 4 separate VBUSM initiator interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A 2 word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

11.1.1.4.1.2 Config CR

The function of the Config CR is to switch transactions which arrive on the configuration interface to the various configuration targets within the DMA. The Config CR also provides a retiming buffer on the configuration bus primary interface ports.

11.1.1.4.1.3 Configuration Registers

The Configuration Registers block is responsible for monitoring the fullness level of the Tx Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Tx PKTDMA core blocks, and writing back the updated state returned from those same DMA core blocks.

The Configuration Registers block is also responsible for providing memory mapped registers for configuration of the Rx DMA functions including the default settings for the free descriptor and destination queues. For modularity and high speed pipelining reasons, the Rx traffic is looped through the Configuration Registers block where the original stream information is merged with information from the configuration registers on its way to the Rx DMA unit module. This prevents the Rx DMA Core from having to spend cycles accessing the channel configuration information for the channel.

11.1.1.4.1.4 Tx Packet DMA Unit

The Tx Packet DMA Unit block implements all of the state machine functionality necessary to implement the KS3 DMA Host Tx protocol. The Tx Packet DMA unit initiates VBUSM transactions in order to read descriptor pointers from the memory mapped Tx ring, read descriptors from memory, and read data from buffers in memory.

11.1.1.4.1.5 Tx Packet Coherency Unit

The Tx Packet Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the Tx DMA unit(s) and that all previous packets on that channel/flow have also completed prior to incrementing the reverse ring occupancy for the channel/flow.

11.1.1.4.1.6 Tx Per Channel Buffers

The Tx Per Channel Buffers implement a FIFO for each Tx DMA channel that is used for buffering packet control and payload data that has been fetched by the Tx Packet DMA units. The buffers are byte oriented on write so that the data from the DMA units which may not be full words can be packed properly. The buffers are block

Copyright © 2024 Texas Instruments Incorporated

oriented on read and each Tx (source) channel in the PKTDMA controller maps directly onto a thread in the Tx PSI interface. The Tx Per Channel Buffer block outputs queue fullness information to the Tx Scheduler block which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Tx Per Channel Buffer will initiate transfers to the target whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round robin arbitration between the different threads for the use of the Transmit PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

11.1.1.4.1.7 Rx Per Channel Buffers

The Rx Per Channel Buffers implement a FIFO for each Rx DMA channel that is used for buffering packet control and payload data that has been pushed into the DMA from the Rx PSI-L interface. The Rx Per Channel Buffers also includes an arbitration unit which determines which Rx DMA channel should be serviced next.

11.1.1.4.1.8 Rx Packet DMA Unit

The Rx Packet DMA Unit block implements all of the state machine functionality necessary to implement the KS3 DMA Rx protocol for Host descriptor types. The Rx Packet DMA Unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read buffer descriptor information, write descriptors to memory, and write data to buffers in memory.

11.1.1.4.1.9 Rx Packet Coherency Unit

The Rx Packet Coherency Unit is responsible for ensuring that all control structures and data have been written by the Rx DMA unit(s) and that all previous packets on that channel/flow have completed prior to incrementing the reverse ring occupancy for the channel/flow. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Rx free queues. Writes are not considered complete by this unit until the entire write status has been returned for all outstanding transactions for a given packet ID.

11.1.1.4.1.10 Event Handler

The Event Handler block is responsible for generating channel completion and error events.

11.1.1.4.2 Channel Classes

Not all channels within the PKTDMA require the same performance capabilities. Raw bandwidth and latency tolerance requirements will vary greatly between data transfers at various points in the system. Due to area concerns, several different classes of DMA channels are provided in the PKTDMA and are described as follows:

Class Name	Description
Normal Capacity	Provides baseline amount of descriptor prefetch and Tx/Rx control and data buffering. Suitable for most peripheral transfers which are communicating with on-chip memories and DDR
High Capacity	Provides an elevated amount of descriptor prefetch and custom Tx/Rx control and data buffering. Suitable for applications which require moderate per-channel bandwidth with significantly increased latency (ex. Transferring data to/from PCIe)
Ultra-High Capacity	Provides identical descriptor and TR prefetch as High Capacity but with increased Tx data buffering to allow for more read data in flight. Suitable for applications requiring high per-channel bandwidth with significantly increased latency (ex. 16+Gbps transfers to/from PCIe).

PKTDMA instances may provide support for any or all of the above channel classes through design time configuration parameters.

11.1.1.5 Block Copy DMA (BCDMA)

The Block Copy DMA is intended to perform similar functions as an Embedded DMA (EDMA) and the UDMA-P. The BCDMA module moves data from a memory mapped source address set to a corresponding memory mapped address. The BCDMA maintains state information for each of the channels which allows data copy operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

A block diagram of the Block Copy DMA Controller is shown below:

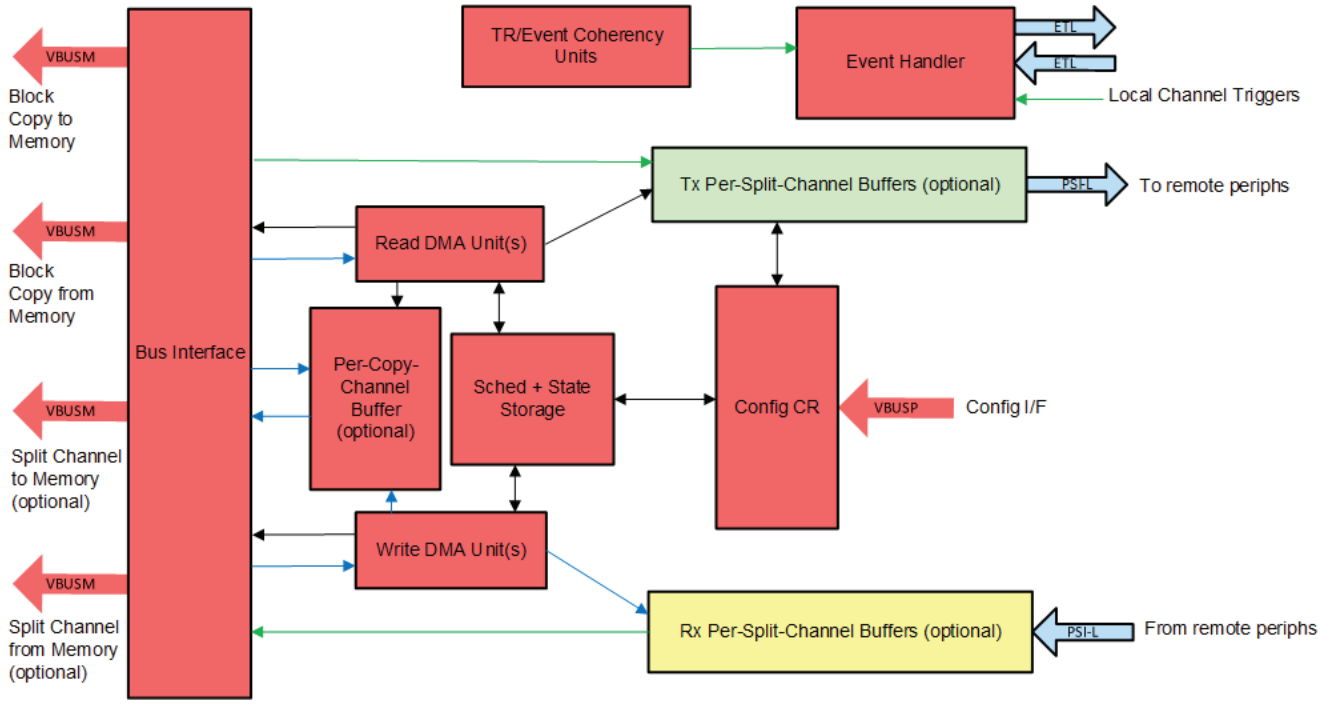

Figure 11-2. Block Copy DMA Block Diagram

11.1.1.5.1 BCDMA Submodule Descriptions

11.1.1.5.1.1 Bus Interface Unit

The Bus Interface Unit is reponsible for merging and buffering all of the transactions that originate from the various controller blocks inside the DMA controller into the 4 seperate VBUSM controller interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A 2 word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

11.1.1.5.1.2 Config CR

The function of the Config CR is to switch transactions which arrive on the configuration interface to the various configuration targets within the DMA. The Config CR also provides a retiming buffer on the configuration bus primary interface ports.

11.1.1.5.1.3 Configuration Registers

The Configuration Registers block is responsible for monitoring the fullness level of the Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Read and Write DMA units, and writing back the updated state returned from those same DMA units.

The Configuration Registers block is also responsible for providing memory mapped registers for configuration of the DMA channels.

Table 11-3. BCDMA Mapping Table (continued)

Total Bits	Bits	Register Offset	Field	Description
399	15	0xB0	sot	

11.1.1.5.1.4 Read Unit(s)

The Read Units implement all of the state machine functionality necessary to perform the read transfers defined in the SW supplied Transfer Request records. The read DMA unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read descriptors, Transfer Request records, and payload data from memory.

11.1.1.5.1.5 TR Coherency Unit

The TR Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the BCDMA unit(s) and all prior TRs have completed prior to incrementing the reverse ring occupancy for the flow/channel.

11.1.1.5.1.6 Per-Copy-Channel Buffers

The Per-Copy-Channel Buffers implement a FIFO for each BCDMA generic block copy channel and is used for buffering payload data that has been fetched by read DMA unit modules. The write DMA units issue write transfers from the Per Channel Buffers to specified addresses in memory. The buffers are byte oriented on both write and read so that the data from the DMA units which may not be full words can be packed and unpacked properly. This unit is optional and is only present if one or more generic block copy channels are configured in the BCDMA instance.

11.1.1.5.1.7 Tx Per-Split-Channel Buffers

The Tx Per-Split-Channel Buffers implement a FIFO for each BCDMA Tx split mode channel and is used for buffering payload data that has been fetched by read DMA unit modules. Data is transferred from the buffer to the remote peripheral via a PSI-L interface. This unit is optional and is only present if one or more Tx split mode channels are configured in the BCDMA instance.

11.1.1.5.1.8 Rx Per-Split-Channel Buffers

The Rx Per-Split-Channel Buffers implement a FIFO for each BCDMA Rx split mode channel and is used for buffering payload data that has been received from remote peripherals via a PSI-L interface. Data is read from these FIFOs and written out to memory as directed by the write DMA unit modules. This unit is optional and is only present if one or more Rx split mode channels are configured in the BCDMA instance.

11.1.1.5.1.9 Write Unit(s)

The Write Units implement all of the state machine functionality necessary to perform the write transfers defined in the SW supplied Transfer Request records. The write DMA unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read descriptors and/or Transfer Request records from memory mapped rings, read descriptor and Transfer Request records, and write payload data to memory.

11.1.1.5.1.10 Event Coherency Unit

The Event Coherency Unit is responsible for ensuring that all writes have completed prior to signaling an output event for a channel/flow.

11.1.1.5.1.11 Event Handler

The Event Handler block is responsible for generating channel completion and error events and for accepting and tracking channel triggering.

11.1.1.5.2 Channel Classes

Not all channels within a DMA controller require the same performance capabilities. Raw bandwidth and latency tolerance requirements will vary greatly between data transfers at various points in the system. Due to area concerns, several different classes of DMA channels are provided in the BCDMA and are described as follows:

Copyright © 2024 Texas Instruments Incorporated

Class Name	Description
Normal Capacity	Provides baseline amount of descriptor and TR prefetch and Tx/Rx control and data buffering. Suitable for most peripheral transfers which are communicating with on-chip memories and DDR
High Capacity	Provides an elevated amount of descriptor and TR prefetch and custom Tx/Rx control and data buffering. Suitable for applications which require moderate per-channel bandwidth with significantly increased latency (ex. Transferring data to/from PCIe)
Ultra-High Capacity	Provides identical descriptor and TR prefetch as High Capacity but with increased Tx data buffering to allow for more read data in flight. Suitable for applications requiring high per-channel bandwidth with significantly increased latency (ex. 16+Gbps transfers to/from PCIe).

BCDMA instances may provide support for any or all of the above channel classes through design time configuration parameters.

11.1.2 Definition of Terms

Host— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.

Channel— A channel refers to the sub-division of information (flows) that is transported across a DMA engine. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (for example, CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). Information flow within a channel is a stream of strongly ordered information.

Data Buffer— A data buffer is a single data structure that contains payload information for transmission to or reception from a channel.

Buffer Descriptor— A buffer descriptor is a single data structure that contains information about one or more data buffers.

Packet Descriptor— A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. All Monolithic type descriptors are packet descriptors (and are also a Data Buffer).

Queue— A queue is a list of strongly ordered entries which is typically used to pass work between a producer and a consumer. Queue entries in most cases are references to a work payload which is being passed, but in some cases, (Transfer Request Packets for example) queue entries may actually contain data which is being transferred. Queues are used throughout DMA whenever communication is required between entities. Queues can have multiple different implementations and DMA uses two of the most common: linked lists and rings.

Linked list— A linked list is a data structure in which each entry stores not only the entry data but also a chaining pointer to the next entry in the list. The last entry in each list has its chaining pointer set to NULL (typically encoded as 0x0). The list manager maintains a pointer to the head element on the list and to the tail element on the list. Since the chaining pointer is stored with the entry data, linked lists have a length which is dynamically changeable and limited only by the ability to allocate additional entries which are to be queued/de-queued. Linked lists are present in Host Descriptors to chain multiple descriptors to form a packet.

Ring— A ring is a data structure in which a contiguous memory block defined by M N-byte entries (total size is M × N bytes) is statically allocated and sequentially written/read in order to pass data or data references. Rings are also referred to as circular buffers because when the last element in the contiguous memory array is written, the pointers wrap back to the beginning address for the ring and start the process all over again. The Ring Accelerator component uses rings in order to implement logical queues.

Copyright © 2024 Texas Instruments Incorporated

Free Descriptor/Buffer Queue— A free descriptor/buffer queue is a list of available descriptors with prelinked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Ring Accelerator.

Free Descriptor Queue— A free descriptor queue is a list of available descriptors that are not yet linked with buffers that are to be used by the receive ports for monolithic type descriptors. Free Descriptor Queues are implemented by the Ring Accelerator.

Packet Queue— A packet queue is a list of valid (that is, populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes. Packet Queues are implemented by the Ring Accelerator.

Memory— Memory is an area of data storage managed by the host. This area is visible to the port as a 64-bit addressable area.

Device Driver— A device driver is application independent software that runs on the host for purposes abstracting the low level hardware so that upper level software can use the hardware without knowing every bit field location or initialization sequence. General device driver functions include port initialization, transmit packet queuing, and receive packet processing.

SOP— Start of Packet. This refers to the descriptor/buffer that is the first buffer in a packet.

MOP— Middle of Packet. This refers to the descriptors/buffers that are neither the first or last buffers in a packet.

EOP— End of Packet. This refers to the descriptor/buffer that is the last buffer in a packet.

11.1.3 DMSS Hardware/Software Interface

The intent of the Data Movement architecture is to provide a uniform HW/SW interface which includes a rich set of mechanisms that SW can make use of to transfer data with low overhead and reasonable complexity. To this goal, the number of components which SW is required to interact with on an ongoing real time basis has been kept to a minimum and is as follows (in order of anticipated frequency of access):

- Interrupt Aggregator
- Packet DMA
- Block Copy DMA

When interrupts are used, the interrupt aggregator will provide the vast majority of interrupt sources from all DMA components in the system. Each non-exception/non-debug packet and TR completion signaling originates from the Interrupt Aggregator and the IA provides a uniform set of MMRs that can be queried to quickly determine the cause of a specific interrupt. Events from PSI-L/ETL components are all routed to the host via the Interrupt Aggregator.

Each PKTDMA and BCDMA instance includes an inbuilt ring control mechanism which is the primary means by which work is sent to or received from these DMAs. Each DMA instance also includes both static configuration type memory mapped registers and some real-time accessible memory mapped registers for monitoring and control of each individual channel.

Memory mapped data structures are used anytime information needs to be passed between components in the system. These components may be hardware or software. The following sections describe the data structures which are used within the DMSS for passing information. These data structures include data buffers, packet descriptors, buffer descriptors, queues (including transmit queues, transmit completion queues, and receive queues) and the configuration MMRs that are provided in the various components. The following sections provide a detailed description of these data structures.

11.1.3.1 Data Buffers

A data buffer is a byte aligned contiguous block of memory used to store payload data. Each buffer is described in an entry in either a packet descriptor or in a buffer descriptor. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 64-bit memory space.

The Buffer Length field of the packet/buffer descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

11.1.3.2 Descriptors

Descriptors are so named because their primary function is to describe other data structures.

The PKTDMA architecture provides for 2 basic types of descriptors whose characteristics are shown in Table *PKTDMA Descriptor Types and Attributes*.

Copyright © 2024 Texas Instruments Incorporated

Table 11-4. PKTDMA Descriptor Types and Attributes

Descriptor Type	Includes Valid Packet Info	Provided # of Slots to Link In External Data	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Packet Descriptor	✓	1	✓	✓	Used to describe packet and SOP buffer in applications that require Host OS compatible data structures (i.e. applications where the descriptors and buffers cannot be managed independently but must instead be pre-linked by the Host software). These applications inherently require a separate descriptor for each buffer.
Host Buffer Descriptor		1		✓	Used to describe non-SOP buffers in applications that require Host OS compatible data structures

As the above table shows, the Host Packet Descriptor provides packet level information that is useful to both the ports and the Host in order to properly process the packet. These descriptors are referred to as Packet Descriptors and will always appear as the first descriptor within a packet.

The PKTDMA allows descriptors to be allocated on 16-byte address boundaries. This is intended to allow for better memory utilization by allowing on-chip descriptors which are not a power of 2 in length to be packed into arrays with little wasted memory space.

Even though descriptors and buffers may be allocated on any 16-byte alignment, careful consideration of the alignment effects should be made based on the storage location and any cache related affects that may exist. If data structures are placed in off-chip SDRAM the burst size and alignment restrictions of the memory devices must be considered in order to avoid performance issues related to continually fetching mis-aligned blocks. In this case, the memory efficiency can be reduced to 50% because 2 memory bank lines are read for every line sized data fetch. Similarly, placing more than one descriptor or buffer object within a single cache line can cause the adjacent object to become corrupted during cache line writeback operations.

Software/application specific control information may be added to the end of any of the packet descriptor types using as many extra words as necessary but the above alignment rules still apply.

The Block Copy DMA architecture provides a single descriptor type whose characteristics are shown in Table *Block Copy DMA Descriptor Types and Attributes*.

Copyright © 2024 Texas Instruments Incorporated

Table 11-5. Block Copy DMA Descriptor Types and Attributes

Descriptor Type	Includes Valid Packet Info	Provided # of Slots to Link In External Data	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Transfer Request Packet Descriptor		0			Used to feed transfer request sequences to the BCDMA

11.1.3.2.1 Host Packet Descriptor

Host Packet Descriptors are designed to be used when the application requires support for true, unlimited fragment count scatter/gather type operations. The Host Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Host Packet Descriptor
- Source and Destination Tags
- Packet Type
- Packet Length
- Protocol Specific Region Size
- Protocol Specific Control / Status Bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet
- Software specific information

Host Packet Descriptors always contain 48 bytes of required information and may also contain optional software specific information and protocol specific information. How much optional information (and therefore the allocated size of the descriptors) is required is application dependent.

The Host Packet descriptor layout is shown below.

Table 11-6. Host Packet Descriptor Layout

Packet Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)
Extended Packet Info Block (Optional) Includes Timestamp and Software Data (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Other SW Data (Optional and User Defined)

Host Packet Descriptors may be linked with zero or more additional Host Buffer Descriptors in a singly linked list fashion to form packets. Each Host Packet consists of a single Host Packet Descriptor followed by a chain of zero or more Host Buffer Descriptors linked together using the Next Descriptor Pointer fields in the descriptors. The last descriptor in a Host packet has a zero Next Descriptor Pointer.

Copyright © 2024 Texas Instruments Incorporated

The ‘Other SW Data’ portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store completely private data. This region is not used in any way by HW components in a PKTDMA system and these modules will not modify any bytes within this region.

The contents of the Host Packet Descriptor words are detailed in Table *Host Packet Descriptor Packet Information Word 0 (PD Word 0)* through Table *Packet Descriptor Protocol Specific Word N*:

Table 11-7. Host Packet Descriptor Packet Information Word 0 (PD Word 0)

Bits	Name	Description	Rx Overwrite
31:30	2'd1	64-bit Host Packet Descriptor Type Identifier	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes
28	RESERVED	-	*Yes*
27:22	Protocol Specific Valid Word Count	This field indicates the valid # of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes … 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is an error. The valid range for an exact packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information.	Yes

Table 11-8. Host Packet Descriptor Packet Information Word 1 (PD Word 1)

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27:24	Protocol Specific Flags	This field contains protocol specific flags / information that can be assigned based on the packet type.	Yes
23:14	RESERVED	-	Yes

Copyright © 2024 Texas Instruments Incorporated

Table 11-8. Host Packet Descriptor Packet Information Word 1 (PD Word 1) (continued)

Bits	Name	Description	Rx Overwrite
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

Table 11-9. Host Packet Descriptor Packet Information Word 2 (PD Word 2)

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = Application specific	Yes
26:16	RESERVED	-	Yes
15:0	RESERVED	-	Yes

Table 11-10. Host Packet Descriptor Packet Information Word 3 (PD Word 3)

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L src_tag field bits 15:8.	Yes
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L src_tag field bits 7:0.	Yes
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L dst_tag field bits 15:8.	Yes
7:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field with the value provided in the PSI-L dst_tag field bits 7:0	Yes

Copyright © 2024 Texas Instruments Incorporated

Table 11-11. Host Packet Descriptor Linking Word 0 (PD Word 4)

Bits	Name	Description	Rx Overwrite
31:0	Next Descriptor Pointer LSB	The 32 LSBs of the 48-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero then the current buffer is the last buffer in the packet. The host sets the Next Descriptor Pointer.	No

Table 11-12. Host Packet Descriptor Linking Word 1 (PD Word 5)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED		No
19:16	Next Descriptor Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA initiators on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	No
15:0	Next Descriptor Pointer MSB	The 16 MSBs of the 48-bit next descriptor pointer. If a specific SoC uses less than 48 bits of address reach the width of this field may be reduced.	No

Table 11-13. Host Packet Descriptor Buffer 0 Info Word 0 (PD Word 6)

Bits	Name	Description	Rx Overwrite
31:0	Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will be written during reception. These are the 32 LSBs of the 48-bit buffer pointer. **THIS Value along with the MSB bits cannot be 0 or the buffer will be seen as a NULL PTR**	Yes

11.1.3.2.2 Host Buffer Descriptor

The Host Buffer Descriptor is identical in size and organization to a Host Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. Host Buffer Descriptors are designed to be linked onto a Host Packet Descriptor or another Host Buffer Descriptor to provide support for unlimited scatter / gather type operations. Host Buffer Descriptors provide information about a single corresponding data buffer. Every Host buffer descriptor stores the following information:

- Pointer to the first valid byte in the data buffer
- Length of the data buffer
- Pointer to the next buffer descriptor in the packet

Host Buffer Descriptors always contain 48 bytes of required information. Since it is a requirement that it is possible to convert a Host descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Host Buffer Descriptors will be allocated using the same sizes as Host Packet Descriptors. The Host Buffer Descriptor layout is shown below.

Table 11-24. Host Buffer Descriptor Layout

Buffer Reclamation Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)

A Host Packet Descriptor and zero or more Host Buffer Descriptors may be linked together using the Next Descriptor Pointer fields to form packets. The last descriptor in a packet has a zero Next Descriptor Pointer. Each Host Buffer descriptor also points to a single data buffer.

The contents of the Host Buffer Descriptor words are detailed in Table *Host Buffer Descriptor Reserved Word 0 (BD Word 0)* through Table *Host Buffer Descriptor Buffer N Info Word 2 (BD Word 8)*:

11.1.3.2.3 Transfer Request Descriptor

The Transfer Request Descriptor contains the following information:

- Indicator which identifies the descriptor as a TR Descriptor
- Set of one or more Transfer Request Records
- Set of one or more Transfer Response Records

Copyright © 2024 Texas Instruments Incorporated

Transfer Request Packet Descriptors always contain 16 bytes of required information and a variable number of Transfer Request / Transfer Response Records (request and response counts match).

The Transfer Request descriptor layout is shown below.

Table 11-34. Transfer Request Packet Descriptor Layout

Packet Info Given via Transfer Request Packet Descriptor Word 0-3 (16 bytes)
Null (0-102 bytes to bring start of TR request array into natural alignment for memory fetch efficiency)
Array of Transfer Request Records
Array of Transfer Response Records

Table 11-35. Transfer Request Packet Descriptor Word 0

Bits	Name	Description	Rx Overwrite
31:30	2'd3	TR Packet Descriptor type.	No
29	RESERVED		No
28:20	Reload Count	Specifies what to do when the last entry is processed in this packet. This field specifies how many times to return to the Reload Index upon reaching the Last Entry. When an internal count is incremented to this value and the TR indicated by the Last Entry has been processed, this packet will be considered complete and the descriptor will be placed back on the return queue specified in Word 2. A value of 0x1FF indicates that a perpetual loop is desired. In this case, the loop count is considered infinite and the internal count will not be incremented. A teardown operation on the channel will cause the loop to be broken at the nearest iteration boundary.	No
19:14	Reload Index	Specifies the value to set the current processing index to when the last entry is processed and the Reload Enable is set to 1. This is basically an absolute index to jump to on the 2**nd** and following passes through the TR packet.	No
13:0	Last Entry	Specifies the index of the last valid entry in this packet	No

11.1.3.3 Transfer Request Record

11.1.3.3.1 Overview

This section describes the standard transfer request (TR) format to initiate a DMA transfer. The TRs can support both half and full duplex with multiple dimensions. Each TR will also generate a TR response. A TR can be sent to the BCDMA either through a TR descriptor using a pass-by-reference ring or as a Direct TR submission using a pass-by-value ring.

Table 11-40. Terms and Definitions

Term	Definition
TR	A transfer request to move data.
CR	A cache operation request. A request to send messages to a specified cache controller to prepare the cache for a future operation.

11.1.3.3.2 Addressing Algorithm

For a basic TR request the same algorithm is used. The innermost loop always consumes physically contiguous elements from memory. Its implicit dimension is 1 byte. The pointer itself moves from fetch to fetch on the maximum byte alignments specified for the BCDMA, in increasing order. In each level outside the inner loop, the loop moves the pointer to a new location based on the size of that loop level's dimension.

11.1.3.3.2.1 Linear Addressing (Forward)

The following code illustrates the basic algorithm for a 4-level loop nest block move. This model assumes that it transfers data 1 byte at a time and the input and output block are the same size in all dimensions.

```
// sptr is a byte pointer.
// dptr is a byte pointer.
// Source address is indirect
if (TR_ISA) {
    sptr = *sptr;
}
// Destination address is indirect
if (TR_IDA) {
    dptr = *dptr;
}
// TR_TRIGX can be selected to come from Global events, Local event, or none.
// Check for trigger of TYPE0
if (TR_TRIG0_TYPE == TYPE0) while(!TR_TRIG0);
if (TR_TRIG1_TYPE == TYPE0) while(!TR_TRIG1);
for (i3 = 0; i3 < ICNT3; i3++)
{
    sptr3 = sptr; // save current position before entering next level
    dptr3 = dptr; // save current position before entering next level
    // Check for trigger of TYPE1
    if (TR_TRIG0_TYPE == TYPE1) while(!TR_TRIG0);
    if (TR_TRIG1_TYPE == TYPE1) while(!TR_TRIG1);
    for (i2 = 0; i2 < ICNT2; i2++) {
        sptr2 = sptr; // save current position before entering next level
        dptr2 = dptr; // save current position before entering next level
        // Check for trigger of TYPE2
        if (TR_TRIG0_TYPE == TYPE2) while(!TR_TRIG0);
        if (TR_TRIG1_TYPE == TYPE2) while(!TR_TRIG1);
        for (i1 = 0; i1 < ICNT1; i1++) {
            sptr1 = sptr; // save current position before entering next level
            dptr1 = dptr; // save current position before entering next level
            // Check for trigger of TYPE3
            if(TR_TRIG0_TYPE == TYPE3) while(!TR_TRIG0);
            if(TR_TRIG1_TYPE == TYPE3) while(!TR_TRIG1);
            for (i0 = 0; i0 < ICNT0; i0++) {
                // BCDMA can combine these in optimized burst aligned accesses.
                *dptr = *sptr;
                sptr = sptr++;
                dptr = dptr++;
            }
        // Update based on saved pointer for this level
        sptr = sptr1 + SDIM1;
```

Copyright © 2024 Texas Instruments Incorporated

```
        dptr = dptr1 + DDIM1;
        }
    // Update based on saved pointer for this level
    sptr = sptr2 + SDIM2;
    dptr = dptr1 + DDIM2;
    }
```

This form of addressing allows programs to specify regular paths through memory in a small number of parameters. Additionally, it allows for various stall points through the loop to allow for hardware or software induced pausing of the transfer. The following section defines these parameters in detail.

11.1.3.3.3 Transfer Request Formats

The BCDMA defines a four-level loop nest for addressing elements within the TR, using the algorithms described in the Addressing algorithm. Most of the fields in the TR template map directly to the parameters in those algorithms.

Table 11-41. Transfer Request Fields

Field Name	Description	Size
FLAGS	TR flags that specify type of TR and how the TR should be handled. It also supports the TR triggering and output events.	32 bits
ICNT0	Total loop iteration count for level 0 (innermost)	16 bits
ICNT1	Total loop iteration count for level 1	16 bits
ADDR	Starting address for the source data or destination data if it is a half-duplex write.	64 bits
DIM1	Signed dimension for loop level 1 for the source data	32 bits
ICNT2	Total loop iteration count for level 2	16 bits
ICNT3	Total loop iteration count for level 3 (outermost)	16 bits
DIM2	Signed dimension for loop level 2	32 bits
DIM3	Signed dimension for loop level 3	32 bits
DDIM1	Signed dimension for loop level 1 for the destination data	32 bits
DADDR	Starting address for the destination of the data	64 bits
DDIM2	Signed dimension for loop level 2 for the destination data	32 bits
DDIM3	Signed dimension for loop level 3 for the destination data	32 bits
DICNT0	Total loop iteration count for level 0 (innermost) used for destination	16 bits
DICNT1	Total loop iteration count for level 1 used for destination	16 bits
DICNT2	Total loop iteration count for level 2used for destination	16 bits

Copyright © 2024 Texas Instruments Incorporated

Table 11-41. Transfer Request Fields (continued)

Field Name	Description	Size
DICNT3	Total loop iteration count for level 3 used for destination	16 bits

The TR assumes all iteration counts as unsigned integers, and all dimensions as signed integers representing byte offsets.

The template above fully specifies the type of elements, length, and dimensions of the transfer.

Since all transfers will not require all the fields the TRs have the type field which allow the number of words required to be sent for the TR to be reduced.

11.1.3.3.4 Flags Field Definition

The next diagram expands the 32-bit FLAGS field. The numbers above each field here indicate bit numbers within the field.

Table 11-42. Transfer Request Template FLAGS Field

31			24	23			16
CONFIGURATION SPECIFIC FLAGS				Reserved			
15			8	7	5	4	3 0
TRIGGER_SIZE1	TRIGGER1	TRIGGER_SIZE0	TRIGGER0	EVENT_SIZE	WAIT	STATIC	TYPE

The flags field fills in the remaining details about the stream, as follows:

Table 11-43. FLAGS Field Descriptions

Bit	Field	Description
0-3	**TYPE**	The TYPE of TR that is being sent 0: One dimensional data move 1: Two dimensional data move 2: Three dimensional data move 3: Four dimensional data move 4: Four dimensional data move with data formatting 5: Four dimensional Cache Warm 6-7: Reserved 8: Four Dimensional Block Move 9: Four Dimensional Block Move with Repacking 10: Two Dimensional Block Move 11: Two Dimensional Block Move with Repacking 12-14: Reserved 15 Four Dimensional Block Move with Repacking and Indirection
4	Reserved	Reserved for Future use.

Copyright © 2024 Texas Instruments Incorporated

Table 11-43. FLAGS Field Descriptions (continued)

Bit	Field	Description
5	WAIT	This field is only valid on Type 15 TRs. This field indicates whether or not this TR should ensure it completes before allowing the next TR to start on this channel. The encoding is as follows: 0 = Allow next TR to start immediately 1 = Wait for this TR to complete before allowing next TR to start When set, the next TR will not be considered triggered (regardless of any other trigger conditions) until all write status responses for the current TR have landed.
6-7	EVENT_SIZE	This is how often the TR will generate an output event. 0: Event is only generated with the TR is complete 1: Event is generated when the second inner most loop (ICNT1) is decremented by 1. 2: Event is generated when the third inner most loop (ICNT2) is decremented by 1. 3: Event is generated when the outer most loop (ICNT3) is decremented by 1.
8-9	TRIGGER0	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER0_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel
10-11	TRIGGER0_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
12-13	TRIGGER1	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER1_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel This field is reserved for a Direct TR.

Copyright © 2024 Texas Instruments Incorporated

Table 11-43. FLAGS Field Descriptions (continued)

Bit	Field	Description
14-15	**TRIGGER1_TYPE**	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
16-23	Reserved	Reserved for Future use.
24-31	**Configuration Specific Flags**	These are flag bits that can be specified by the specific BCDMA configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific BCDMA implementation.

The following sections expand on each of these fields.

11.1.3.3.4.1 Type: TR Type Field

The TR Type field gives the size of the TR and which fields are expected in the TR. Based on the type the number of words required to be sent to complete the TR can be decreased. The tables below show the minimum size for each TR as well if any fields will be treated as reserved.

Table 11-44. Transfer Request Minimum Size Type 0 One Dimensional Transfer

11.1.3.3.4.2 EVENT_SIZE: Event Generation Definition

The BCDMA allows for an event to be generated at specified intervals for each TR. As the TR passes through the various loops in the addressing algorithm it will generate an event that then can be routed to other event receivers, such as other channels or interrupts to processors.

Table 11-49. Event Size Encoding

Value	Event Type	When it Fires
0	Completion Event	When the TR is complete and all status for the TR has been received.
1	ICNT1 Decrement	Type 0: When the last data transaction is sent for the TR. Type 1-11: When ICNT1 is decremented
2	ICNT2 Decrement	Type 0 – 1,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT2 is decremented
3	ICNT3 Decrement	Type 0 – 2,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT3 is decremented

11.1.3.3.4.3 TRIGGER_INFO: TR Triggers

The TR allows for two different triggers to be set to allow for the data transfer to be prevented or halted through the process of transferring the data. The triggers are specified by selecting a type of trigger and the size of the transfer that can be allowed for the receipt of a given trigger. The triggers themselves in the BCDMA are collected on a per channel basis and for each of three sources. Anytime the trigger event is received the internal counter is incremented. The trigger event will not be cleared until the specified block has started its transfer and it will **only** clear the triggers that are active.

CAUTION

This does allow for one TR in the channel to use global event 0 and the next TR to use global event 1. If while the first TR is running global event 0 can increment and will decrement each time the TR reaches the specified level. At the same time global event 1 will be incremented whenever it is received but it will not decrement until the next TR runs. If the global event 1 counter reaches overflows then an error event will NOT be generated but the event will be lost.

11.1.3.3.4.4 TRIGGERX_TYPE: Trigger Type

The trigger type sets the value of TR_TRIGX as shown in the addressing algorithm description. The TR_TRIGX value allows for the temporary halting of the TR until the expected event has been received. After the given loop has been entered the selected trigger will be decremented.

Copyright © 2024 Texas Instruments Incorporated

11.1.3.3.4.5 TRIGGERX: Trigger Selection

The TR is able to select up to 2 of 3 trigger sources for a given TR. The events can come from the dedicated local event on the BCDMA itself or from two assigned global events that come from the PSI-L interface on the BCDMA. The trigger counters are always enabled so that events can be received prior to the TR getting loaded. The trigger counters are only decremented when the trigger is active and the TR has scheduled the first transfer of the transaction.

11.1.3.3.4.6 Configuration Specific Flags Definition

The configuration specific flags are specific to a given TR type. If a TR type does not require additional flags the field should be filled with 0's. Currently only Types 0-4 and Type 15 support the following configuration specific flags:

Bit	Field	Description
0	**ISA**	Indirect Source Address 0: Source address in TR is a directly usable pointer to the data 1: Source address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
1	**IDA**	Indirect Destination Address 0: Destination address in TR is a directly usable pointer to the data 1: Destination address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
2	**SUPR_EVT**	Suppress Event Output: 0 = Output events will be generated according to FLAGS.EVENT_SIZE field 1 = No output events will be generated for the duration of this TR execution This field is only valid on split and type 15 TRs (Type 0-3,15)
3	**Reserved**	Reserved for Future use.

Copyright © 2024 Texas Instruments Incorporated

Bit	Field	Description
6:4	EOL	This field is only valid on split TRs (Type 0-3). On source (Read) split TRs, this field specifies whether or not the EOL delimiters should be produced on the Tx PSI-L bus. The encodings of this field for source split TRs is as follows: 0 = SOL/EOL match SOP/EOP 1 = SOL/EOL boundaries are each ICNT0 bytes 2 = SOL/EOL boundaries are each ICNT0*ICNT1 bytes 3 = SOL/EOL boundaries are each ICNT0*ICNT1*ICNT2 bytes 4 = SOL/EOL boundaries are each ICNT0*ICNT1*ICNT2*ICNT3 bytes On destination (Write) split TRs, this field specifies how to handle EOL delimiters when they are encountered on the Rx (write) side of a TR. EOL delimiters can be produced from the Tx (read) side of a block copy operation or from a remotely paired peripheral when operating in split TR mode. The encodings of this field are as follows: 0: Ignore EOL 1: Line length is icnt0 bytes. Clear any remaining ICNT0 bytes and increment ICNT1 by 1 2: Line length is icnt0*icnt1 bytes. Clear any remaining ICNT0/1 bytes and increment ICNT2 by 1 3: Line length is icnt0*icnt1*icnt2 bytes. Clear any remaining ICNT0/1/2 bytes and increment ICNT3 by 1 4: Line length is icnt0*icnt1*icnt2*icnt3 bytes. Move on to next TR 5-7: RESERVED
7	EOP	This TR should generate an EOP on the streaming interface for any downstream packet oriented consumers to denote that a ‘packet’ of data is complete 0: No EOP flag will accompany the last PSI-L data phase associated with transfers from this TR 1: On egress the DMA will set the EOP flag coincident with transferring the last of the data for this TR. If the TR data does not complete an entire PSI-L data phase then the remaining bytes in the data phase will be skipped and the internal FIFO pointer will be updated to begin packing new data on a new data phase boundary.

Copyright © 2024 Texas Instruments Incorporated

11.1.3.3.5 TR Address and Size Attributes

The fields described below all describe the data transfer that needs to be made as described in the Linear Memory Addressing Block Move Algorithm.

11.1.3.3.5.1 ICNT0

The ICNT0 is the number of elements to transfer in the inner loop of the TR. If the TR type does not contain a FMTFLAGS field then this count is assumed to be the number of bytes to transfer. If the FMTFLAGS field is included in the types then the number of bytes to be transferred will be ICNT0 times the Element size rounded up to the nearest byte.

11.1.3.3.5.2 ICNT1

The ICNT1 field is the loop count for the second innermost loop count as defined in the Addressing algorithm.

11.1.3.3.5.3 ADDR

The address location is the initial address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register.

While the ADDR field is 64 bits wide, the usable extent of the address is up to 48 bits of absolute offset plus a 4-bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the ADDR field is given as follows:

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA initiators on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other ‘tiles’ on large devices.
47:0	Address	The 48-bit source or source starting address for the transfer. This address is assumed to be a physical address. The actual width implemented for the address field on any given DMA instance may be adjusted to the needs of each specific KSLC SoC. 48 bits is just the maximum size which is envisioned to be supported. Some systems may have address widths as low as 32 or 36 bits. The HW implementation may choose to provide address width configurability in order to reduce costs.

11.1.3.3.5.4 DIM1

This is the offset of the address from the initial address for the first access of the second loop. This will be added to the address from the loop before. This is a signed value so that the address can be both above and below the initial address.

Copyright © 2024 Texas Instruments Incorporated

11.1.3.3.5.5 ICNT2

This is the count for the third innermost loop in the addressing algorithm.

11.1.3.3.5.6 ICNT3

This is the count for the outermost loop in the addressing.

11.1.3.3.5.7 DIM2

This is the offset of the address from the initial address to the next address in the third innermost loop. This is a signed value so that the address can be both above and below the previous address.

11.1.3.3.5.8 DIM3

This is the offset of the address from the initial address to the next address in the outermost loop. This is a signed value so that the address can be both above and below the previous address.

11.1.3.3.5.9 DDIM1

This is the offset of the destination address from the initial destination address for the first access of the second loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

11.1.3.3.5.10 DADDR

The destination address location is the initial destination address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register

While the DADDR field is 64 bits wide, the usable extent of the address on a KSLC system is up to 48 bits of absolute offset plus a 4 bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the DADDR field is given as follows:

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA initiators on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other ‘tiles’ on large devices.
47:0	Address	The 48-bit starting destination address for the transfer. This address is assumed to be a physical address. The actual width implemented for the address field on any given DMA instance may be adjusted to the needs of each specific KSLC SoC. 48 bits is just the maximum size which is envisioned to be supported. Some systems may have address widths as low as 32 or 36 bits. The HW implementation may choose to provide address width configurability in order to reduce costs.

Copyright © 2024 Texas Instruments Incorporated

11.1.3.3.5.11 DDIM2

This is the offset of the destination address from the initial destination address for the first access of the third loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

11.1.3.3.5.12 DDIM3

This is the offset of the destination address from the initial destination address for the first access of the outer loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

11.1.3.3.5.13 DICNT0

This is the number of elements to use in the destination if the TR is repacking the data. This number reflects the number of elements to be transferred.

11.1.3.3.5.14 DICNT1

This is the number of times to execute the second loop to use in the destination transfer.

11.1.3.3.5.15 DICNT2

This is the number of times to execute the third loop to use in the destination transfer.

11.1.3.3.5.16 DICNT3

This is the number of times to execute the fourth loop to use in the destination transfer. The value of DICNT0 x DICNT1 x DICNT2 x DICNT3 must equal ICNT0 x ICNT1 x ICNT2 x ICNT3. If any of the values are zero they are NOT included in the multiplication.

11.1.3.4 Transfer Response Record

Upon completing a TR, the BCDMA will send back a TR Response. The BCDMA TR response format is a single 32 bit word as shown in the Table 11-51 below.

Table 11-50. Transfer Request Response Template STATUS FLAGS Field

31	24	23	16
CONFIGURATION SPECIFIC STATUS		RESERVED	

15	8	7	7	4	3	0
RESERVED		STATUS_INFO			STATUS_TYPE	

Table 11-51. STATUS FLAGS Field Descriptions

Bit	Field	Description
3:0	**STATUS_TYPE**	The completion status of the TR.
7:4	**STATUS_INFO**	Information that is unique based on the STATUS_TYPE returned
15:8	**Reserved**	Reserved for Future use
23:16	**Reserved**	Reserved for Future use

Copyright © 2024 Texas Instruments Incorporated

Table 11-51. STATUS FLAGS Field Descriptions (continued)

Bit	Field	Description
31:24	Configuration Specific Flags	These are flag bits that can be specified by the specific BCDMA configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific BCDMA implementation. For BCDMA channels which are capable of interfacing to endpoint peripherals (or via a PDMA) the format of these flags are as follows: 31:28 error_flags – the error_flags field as is provided across PSI-L 27:24 ps_flags – the ps_flags field as is provided across PSI-L

11.1.3.4.1 STATUS Field Definition

The Status field is made up of two sub-fields STATUS_TYPE and STATUS_INFO. A value of 0 means it completed as requested any other value means an error has occurred. The Table below states the legal STATUS_TYPEs and the use of the STATUS_INFO in each case.

11.1.3.4.1.1 STATUS_TYPE Definitions

The STATUS_TYPE field is used to determine what type of status is being returned. Depending on the type of Status it might additionally have information in the STATUS_INFO to give more details about the specific reason why the status was returned.

Table 11-52. STATUS_TYPE Encoded Values

Value	Error Type	Completion	STATUS INFO Definition
0	None	Complete	None
1	Transfer Error	None to Partial	CBA Non-Complete Status Received
2	Aborted Error	None to Partial	None
3	Submission Error	None	Submission Error Type
4	Unsupported Feature	None	Feature Type
5	Transfer Exception	Partial	Exception Type
6	Teardown Flush	None	None
7-15	Reserved	Unknown	Reserved

11.1.3.4.1.1.1 Transfer Error

A transfer error occurs anytime that one of the CBA transactions performed by the BCDMA returns a status other than complete. The BCDMA may continue the transfer or may abort the transfer and return back to an IDLE state. Once the transfer is finished (aborted or complete) the BCDMA will send back the TR Response with the STATUS TYPE of Transfer Error. The STATUS INFO will contain the 3 bit CBA Status field the upper bit specifies if it was a read status (1) or a write status (0).

11.1.3.4.1.1.2 Aborted Error

An aborted error occurs if the PSI-L interface asserts the drop signal prior to the completion of the TR. The BCDMA will return back to an IDLE state and send back the TR Response with the STATUS TYPE. If the

Copyright © 2024 Texas Instruments Incorporated

BCDMA receives a transfer error after receiving the abort the transfer error should be reported instead of the abort error.

11.1.3.4.1.1.3 Submission Error

A submission error is returned for a TR that is received that cannot be run. The STATUS_INFO field specifies the type of submission errors.

Table 11-53. Submission Error STATUS_INFO Encodings

Value	Submission Error Type
0	ICNT0 was 0
1	Channel FIFO was full when TR received
2	Channel is not owned by the submitter. Either CC submitting to Direct or Direct submitting to a CC channel
3	Reserved
4	Reserved
5	Bad descriptor type
6-15	Reserved

11.1.3.4.1.1.4 Unsupported Feature

An unsupported feature error is returned for a TR that is received that cannot be run because it specifies a feature that is optional and not supported by the BCDMA that received the TR. The STATUS INFO specifies the feature that was not supported. If it specifies multiple features that were not supported the BCDMA implementation can determine which type it wants to return.

Table 11-54. Unsupported Feature STATUS_INFO Encodings

Value	Submission Error Type
0	TR Type not supported
1	STATIC not supported
2	EOL not supported
3	CONFIGURATION SPECIFIC not supported
4	AMODE not supported
5	ELTYPE not supported
6	DFMT not supported
7	SECTR not supported
8	AMODE SPECIFIC Field not supported
9-15	Reserved

11.1.3.4.1.1.5 Transfer Exception

A transfer exception is returned for a TR that completed but experienced a known exception during reception. The STATUS_INFO field specifies the type of transfer exception that was encountered.

Table 11-55. Transfer Exception STATUS_INFO Encodings

Value	Transfer Exception Type
0	EOP on incoming data stream was encountered prematurely (short packet)
1	EOP on incoming data stream was encountered late (long packet)

Copyright © 2024 Texas Instruments Incorporated

Table 11-55. Transfer Exception STATUS_INFO Encodings (continued)

Value	Transfer Exception Type
2-15	Reserved

11.1.3.4.1.1.6 Teardown Flush

Split mode BCDMA Rx channels (write channels) can respond with a teardown flush in the case that they have received a teardown message, all data has been transferred , and TRs have been prefetched (in anticipation of more data being received). In this case, the BCDMA will simply return the prefetched TR to the completion queue with the status type set to teardown flush.

11.1.3.5 Channels

Each DMA controller instance contains one or more channels. A channel represents a single thread of strongly ordered operations whose purpose is to move data from one interface to another. Operations between channels are orthogonal and have no assumption of ordering but operations within a channel must be completed in order. The DMA controller uses time division multiplexing to allow work from channels to momentarily use shared data transfer units and data paths.

11.1.3.6 Flows

Each DMA channel will provide one or more flows which allow communication with one or more SW hosts. Each flow contains a single queue pair implemented within a shared circular buffer (ring) in memory. One queue provides uni-directional communication from SW to the DMA while the other queue provides uni-directional communication from the DMA back to SW. Flows are intended to allow traffic which is produced or consumed by a different Host SW process or traffic which is on different priorities to share a single physical DMA channel. A DMA channel will perform time division multiplexing between flows on specific work boundaries. Once a channel is in work on a specific flow, that entire unit of work will be completed before allowing work from a different flow to begin.

11.1.3.7 Queues

Queues are used to hold either values or references that need to be passed between SW and HW components in the system. Queues are implemented in the PKTDMA and BCDMA modules using memory mapped rings. Each ring is comprised of a single contiguous memory block which contains an array of elements. Each element is 8 bytes. The size of the ring is selectable from 1 entry up to 64K entries with single entry granularity. Each ring is used to implement a forward and a reverse queue which share the same data elements but which have independent pointers and occupancies. The forward queue is used to pass work from SW to HW and the reverse queue is used to pass completed work back from HW to SW. A doorbell MMR is provided per ring to allow SW to add elements to the forward queue. A separate doorbell MMR is provided per ring to allow SW to acknowledge the popping of elements from the reverse queue. An occupancy MMR is provided for the reverse queue so that SW can know how many entries are currently completed. Entries are returned on the reverse queue in the exact same order and in the exact same index as the work was provided on the forward queue and because of this, the DMA controllers do not actually modify the ring entry for completion operations (the only exception being for acknowledgement of a teardown operation). Completion is indicated by incrementing of the reverse occupancy only.

11.1.3.7.1 Queue Types

11.1.3.7.1.1 Transmit Queues

Tx channels use packet queues referred to as “transmit queues” to store the packets that are waiting to be transmitted. Tx Queues only pass a pointer to a descriptor. For the PKTDMA, Tx Queues contain pointers to Host descriptors. For the BCDMA, pass Tx Queues contain a pointer to a TR packet descriptor. Transmit Queues are implemented as the forward queue on the shared ring structure for a Tx flow.

Copyright © 2024 Texas Instruments Incorporated

11.1.3.7.1.2 Transmit Completion Queues

Tx channels also use packet queues referred to as “transmit completion queues” to return packets to the host after they are transmitted. A Tx Completion Queue is provided for each Tx Queue. The DMA controllers do not actually write anything back to completion queues (except for a teardown acknowledgement) but instead just increment the reverse occupancy. Transmit completion queues are implemented as the reverse queue on the shared ring structure for a Tx flow.

11.1.3.7.1.3 Free Descriptor / Buffer Queues

Free descriptor/buffer queues pass an empty list of pre-chained descriptors, each pointing to a single buffer, from SW to the DMA to use for receiving incoming packets. Free Descriptor/Buffer Queues are implemented as the forward queue on the shared ring structure for an Rx flow.

11.1.3.7.1.4 Receive Queues

Rx queues pass a packet which has been received from the DMA back to the SW. Receive queues are implemented as the reverse queue on the shared ring structure for an Rx flow.

11.1.3.7.1.5 Ring Based Queues Implementation

Work packets which are stored in a queue are shown in the following diagram:

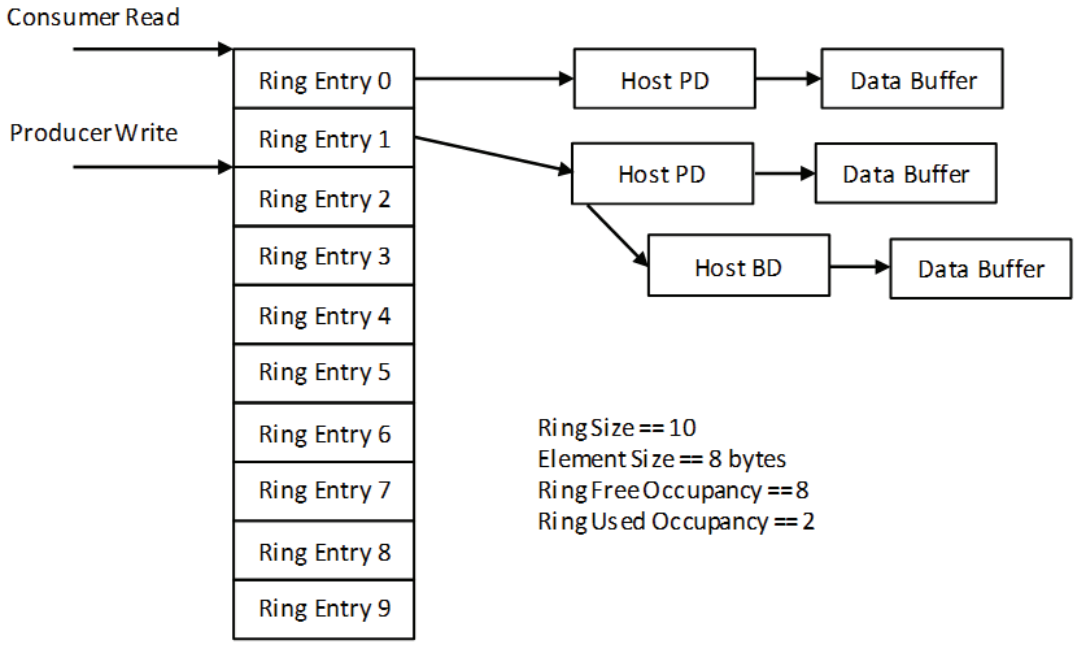

Figure 11-3. Ring Based Queue Structure

11.1.4 Operational Description

11.1.4.1 Resource Allocation

Rings, memory, interrupts, DMA channels, and flow table entries are shared resources within the data movement architecture and their ownership and use must be managed in order to provide stable, safe, and secure operation. The DMSS provides channelized firewalls which can be used to protect arrayed resources (like rings, channel control MMRs, etc.) from unwanted/unauthorized use as well as restricted access to the firewall configurations themselves. It is outside the scope of this document to define how the resource management system functions but it is assumed that all of these resources are isolate-able and secure-able.

Copyright © 2024 Texas Instruments Incorporated

11.1.4.2 PKTDMA/BCDMA - Ring Operation

11.1.4.2.1 Queue Initialization

The base address and size for each ring must be initialized via the provided MMRs prior to using the ring. Ring initialization is typically done only on channel / flow setup as once initialized the rings can be used indefinitely.

11.1.4.2.2 Queueing Entries

Entries can only be queued by SW onto the forward queue of a ring. To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor or a TR) to the memory location pointed to by the current write pointer and will decrement its internally maintained free entry occupancy. After the producer has confirmed that the data has actually landed it memory, it will then write to the forward doorbell register (RINGRT[a]_RT_FDB) for the ring to increment the pending forward occupancy count for the ring.

More than one entry can be queued with a single doorbell write as the entry count in the doorbell write indicates how many entries have been queued.

11.1.4.2.3 De-queueing Entries

Entries can only be de-queued by SW from the reverse queue of a ring. The consumer (entity which is going to de-queue an entry from the ring) maintains a current read pointer for each ring it controls. To de-queue an entry the consumer will read the occupancy from the reverse occupancy register (RINGRT[a]_RT_ROCC) and will then read the entry contents from the memory location pointed to by the current read pointer. The consumer will then write a decrement value to the reverse doorbell register (RINGRT[a]_RT_ROCC) for the ring to decrement the waiting occupancy count for the reverse queue within the ring and will increment its internally maintained free entry occupancy for the ring.

11.1.4.3 PKTDMA/BCDMA - Output Event Generation

Each channel and flow within a DMA has the ability to generate specific types of events which can be routed to the IA in the system and from there re-routed to any event consumer. Events are output from the DMA controllers using a simple integer encoding. Up to 4 events can be generated from any given channel but only event types which have functional value are supported on each specific type of channel. The DMA channel event types are listed as follows:

Table 11-56. Per-Channel/Flow Event Support and Encoding

Name	Description	Per	BCDMA BC	BCDMA Tx	BCDMA Rx	PKTDMA Tx	PKTDMA Rx
Ring Entry Zero/Non-zero	Asserts an up event anytime the ring transitions to a non-zero occupancy / teardown state. Asserts a down event anytime the ring transitions to a zero occupancy / teardown state.	Flow	X	X	X	X	X

Copyright © 2024 Texas Instruments Incorporated

Table 11-56. Per-Channel/Flow Event Support and Encoding (continued)

Name	Description	Per	BCDMA BC	BCDMA Tx	BCDMA Rx	PKTDMA Tx	PKTDMA Rx
Channel Error	Asserts an up event anytime an error occurs on the channel. Asserts a down event when the channel error bit is cleared.	Channel	First flow in channel only	First flow in channel only	First flow in channel only	First flow in channel only	First flow in channel only
Rx Starvation	Asserts an up event when starvation occurs on a flow. Asserts a down event when entries are added to the ring for that flow.	Flow					First flow in channel only
RX Flow FW Error	Asserts an up event when a flow id arrives on the RX interface that is not between the flowid_start and flowid end values for the channel. Asserts a down event when the RX Flow ID Firewall Status Register pend bit is cleared	Pktdma					X
Data Events	Asserts an up event when the selected loop counter has decremented. If the suppress event bit is not set in the TR	Channel	X	X	X		

Each BCDMA/PKTDMA instance will provide an event transport-lane (ETL) interface to pass outgoing events. The index field on this ETL will be calculated based on the event type and channel or flow offset. Each PKTDMA or BCDMA instance is configured with base values to which a channel or flow index is added for each type of event which can be generated. These base index values are listed in the specification for that specific instantiation of each DMA and are named as follows:

Copyright © 2024 Texas Instruments Incorporated

Table 11-57. BCDMA/PKTDMA Event Base Index Parameters

DMA	Event Base Parameter Name	Function	Offset
PKTDMA	tcomp_evtbase	Base index for Tx flow reverse ring completion events	Tx flow number
	rcomp_evtbase	Base index for Rx flow reverse ring completion events	Rx flow number
	terr_evtbase	Base index for Tx channel error events	Tx channel number
	rerr_evtbase	Base index for Rx channel error events	Rx channel number
	rstarve_evtbase	Base index for Rx flow starvation events	Rx flow number
	rflowfw_evtbase	Base index for Rx Flow Firewall event	None
BCDMA	tcomp_evtbase	Base index for split Tx flow reverse ring completion events	Tx flow number
	rcomp_evtbase	Base index for split Rx flow reverse ring completion events	Rx flow number
	bcomp_evtbase	Base index for normal Block Copy flow reverse ring completion events	BC flow number
	terr_evtbase	Base index for split Tx channel error events	Tx channel number
	rerr_evtbase	Base index for split Rx channel error events	Rx channel number
	berr_evtbase	Base index for normal Block Copy channel error events	BC channel number
	tdcomp_evtbase	Base index for Tx channel TR data completion events	Tx channel number
	rdcomp_evtbase	Base index for Rx channel TR data completion events	Tx channel number
	bdcomp_evtbase	Base index for Block Copy channel TR data completion events	BC channel number

Example:

The producer event map is set up so that the Tx flows from a PKTDMA instance are to start at 64 and proceed upward from there. The tcomp_evtbase for that PKTDMA instance is set to 64. In this configuration, the reverse ring entry completion event for flow 0 will produce an event on index 64, flow 1 will produce an event on index 65, etc. The terr_evtbase for the same PKTDMA instance is set to 128. In this configuration, error events for channel 2 would produce events with an index of 130.

11.1.4.4 PKTDMA - Transmit Channel Setup

This section describes the setup procedure for Tx channels within the PKTDMA. After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by configuring all of the Tx flow entries for the channel and then writing to the Tx Channel Configuration Register A (TCHAN[a]_TCFG). The Host may choose to write

Copyright © 2024 Texas Instruments Incorporated

the enable bit in the Tx Channel Configuration Register A (TCHAN[a]_TCFG) at the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

11.1.4.5 PKTDMA - Transmit Channel Pause

Setting the tx_pause bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]_TRT_CTL > [29] TX_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overrun conditions from a downstream data sink or upstream data source.

11.1.4.6 PKTDMA - Transmit Channel Teardown

This section describes the teardown procedure for internal Tx channels within the PKTDMA. A Tx channel teardown is initiated by the host by writing the tx_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]_TRT_CTL > [30] TX_TEARDOWN).

Once the host has written the tx_teardown bit, the PKTDMA will do the following:

1. Stops performing any additional descriptor fetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR fetch has already been performed.
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Global Configuration Register (<TCHANRT[a]_TRT_CTL> [31] TX_ENABLE).
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
7. If the current Tx reverse ring occupancy is 0, issues an Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
8. If the current TX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
9. The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The Host can determine that a teardown is complete by using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) for the channel.

11.1.4.7 PKTDMA - Transmit Operation

After a channel has been set up it can begin to be used to transmit packets. Packet transmission involves the following steps:

1. The Host is made aware of one or more chunks of data in memory that need to be transmitted as a packet. This may involve directly sourcing data from the Host or it may involve data which has been forwarded from another data source in the system.
2. The Host allocates and populates a host packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to Host).

Copyright © 2024 Texas Instruments Incorporated

   b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
   c. Source Tag.
   d. Destination Tag.
   e. Packet Type.
   f. Any protocol specific flags for the given packet type.
   g. Buffer Pointer with the byte aligned address of the first chunk of buffer data.
   h. Buffer Length with the number of bytes in the first chunk of buffer data.
   i. The Next Descriptor Pointer with the 16-byte aligned address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero.
   j. Any protocol specific descriptor sections that are required for the given packet type or system configuration.
3. The Host allocates and populates host buffer descriptors as necessary to point to any remaining chunks of data that belong to this packet. The host will initialize the following fields within the host buffer descriptor:
   a. Buffer Pointer with the byte aligned address of the given chunk of buffer data.
   b. Buffer Length with the number of bytes in the given chunk of buffer data.
   c. The Next Descriptor Pointer with the 16-byte aligned address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero.
4. The Host writes queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue (if more than 1 flow is provided) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller / scheduler implementation.
5. The PKTDMA internally generates a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
6. The PKTDMA Tx engine is eventually brought into context for the corresponding channel and begins to process the packet.
7. The PKTDMA reads the packet descriptor pointer from the memory mapped ring for that channel/flow.
8. The PKTDMA reads the packet descriptor from memory.
9. The PKTDMA empties each buffer in sequence by transmitting the contents in one or more block data moves. The size of these blocks is application specific. The PKTDMA module specification is intended to document the block size used by a given implementation. As each buffer is emptied, the PKTDMA will read the next buffer descriptor to obtain the pointer and size of the data buffer as well as the pointer to the next descriptor in the chain.
10. When all data for the packet has been transmitted as specified in the packet size field, the DMA will increment the occupancy of the reverse queue (Tx Completion Queue).
11. After the occupancy is incremented, the PKTDMA will indicate the status of the Tx Completion Queue by sending an up event.
12. The Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register (VINT[a]_STATUS_SET) as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
13. The Host responds to the status change from the PKTDMA (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. During garbage collection the Host will write to the reverse queue Doorbell register (RINGRT[a]_RT_RDB) for the channel/flow to acknowledge the popping of those completed packets. The doorbell writes eventually cause the queue to become empty.
15. The PKTDMA will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register (VINT[a]_STATUS) and potentially de-assert the interrupt line.

11.1.4.8 PKTDMA - Receive Free Descriptor / Buffer Queue Setup

The Host is ultimately responsible for providing all of the free descriptors and buffers that the port uses as it receives packets. Each entry on the Rx Free Descriptor/Buffer Queue consists of one or more descriptors chained together with each descriptor also pointing to a single contiguous buffer. Each entry on the Rx Free

Copyright © 2024 Texas Instruments Incorporated

Descriptor/Buffer queue is intended to receive one packet of data. All chaining of descriptors within a packet is performed prior to placing the Rx resources onto the free queues.

Before the Host adds each Rx buffer descriptor chain to the queue, it must first initialize the Rx buffer descriptor values as follows:

- Write the Buffer Pointer with the byte aligned address of the buffer data
- Write the Buffer Size
- Write the next descriptor pointer to the next descriptor in the chain (non-eop) or to 0x0 (eop)

All other fields in the Descriptor do not need to be initialized as they will be overwritten by the Port on reception.

11.1.4.9 PKTDMA - Receive Channel Setup

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register (<RCHANRT[a]_RRT_CTL> [31] RX_ENABLE) at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

11.1.4.10 PKTDMA - Receive Channel Teardown

An Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408 . This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the PKTDMA receives a data phase with the tdown attribute asserted it will immediately set the internal rx_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]_RRT_CTL> [30] RX_TEARDOWN).

Once a teardown has been initiated, the PKTDMA will do the following:

1. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
2. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]_RRT_CTL> [31] RX_ENABLE)**>**.
3. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
4. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register to indicate that a teardown has completed (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE).
5. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
6. If the current RX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the PKTDMA. If that is not possible, the host may write the rx_teardown bit directly to a 1.

The Host determines that a teardown is complete by using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) for the channel.

Copyright © 2024 Texas Instruments Incorporated

11.1.4.11 PKTDMA - Receive Channel Pause

Setting the rx_pause bit in the Rx Channel N Control Register (<RCHANRT[a]_TRT_CTL> [29] RX_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overrun conditions from a downstream data sink or upstream data source.

11.1.4.12 PKTDMA - Receive Operation

When packet reception begins on a given channel, the port will begin by fetching the descriptor and buffer from the ring for the channel / flow. If the SOP Buffer Offset in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port will then continue filling that buffer and will fill additional descriptors + buffers as needed using the pre-linked buffers in the packet.

A detailed summary is as follows:

1. Host allocates, populates, and places pointers to free descriptor/buffer structures onto Rx Free Descriptor/ Buffer Queues
2. PKTDMA fetches packet descriptor pointer from forward queue of ring for specified channel.
3. PKTDMA reads the packet descriptor to obtain the packet info, buffer pointer, buffer size, and next descriptor pointer.
4. PKTDMA fills the buffer with received data

If packet is not complete and the rx_chan_type field in the Rx Channel Configuration Register (<RCHAN[a]_RCFG> [19:16] RX_CHAN_TYPE) is set to 2 (Normal Rx Host Mode). The machine will proceed to step 5 and will repeat steps 5-6 until all packet data is received at which point the Rx engine proceeds to step 8. If the rx_desc_type is set to 3 (Single Buffer Packet Host Mode) the Rx engine will proceed directly to step 7 regardless of whether or not an end of packet terminator has been reached on the incoming data stream. The current packet will be completed following the sequence through step 12 and a new packet will be started back at step 1.

5. PKTDMA fetches next buffer descriptor using next descriptor pointer obtained from previous descriptor.

6. PKTDMA fills the buffer with received data.

The PKTDMA performs the following operations when the entire packet has been received:

7. PKTDMA writes the packet descriptor to memory. This includes the following fields:

a. Descriptor Type (set to Host)

b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.

c. Source Tag

d. Destination Tag

e. Packet Type

f. Any protocol specific flags for the given packet type

g. Any protocol specific words that are required for the given packet type

h. Extended Packet Information (optional)

8. PKTDMA increments the occupancy of the reverse queue for the channel / flow.

9. Once the occupancy is incremented it will send an up event to the Interrupt Aggregator

10. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register (VINT[a]_STATUS_SET) indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host

11.The Host will pop the packet pointer from the Rx Queue by reading the ring contents and then pushing a decrement to the reverse occupancy for the ring.

Copyright © 2024 Texas Instruments Incorporated

12. If the pop causes the queue to become empty, the PKTDMA will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

11.1.4.13 BCDMA - Block Copy Channel Setup

This section describes the setup procedure for channels within the BCDMA. After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Port DMA State. The host initializes the channel Port DMA State by initializing all of the channel flow entries and then writing to the Block Copy Channel Configuration Register A (BCHANRT[a]_TRT_CTL). The Host may choose to write the enable bit in the Block Copy Channel Configuration Register A (<BCHANRT[a]_TRT_CTL> [31] TX_ENABLE) at the same time or after it has written all of the channel parameters but note that every write to the Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

After a channel has been set up, packets can be added to the Queues for the channel to begin the copy operation.

For general purpose block copy channels, only the Block Copy DMA configuration, flow, and real-time registers will be present. For split mode channels, separate Tx and Rx configuration, flow, and real-time registers are provided. In all cases, configuration of all fields must be completed before a channel is enabled.

11.1.4.14 BCDMA - Block Copy Channel Pause

Setting the pause bit in the Channel N Control Register (<BCHANRT[a]_TRT_CTL> [29] TX_PAUSE]) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events.

11.1.4.15 BCDMA - Block Copy Channel Teardown

This section describes the teardown procedure for generic block copy channels within the BCDMA. A channel teardown is initiated by the host by writing the teardown bit in the Channel N Real-time Control Register (<BCHANRT[a]_TRT_CTL> [30] TX_TEARDOWN). When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the forced_teardown bit in the Channel N Real-time Control Register (<BCHANRT[a]_TRT_CTL> [28] TX_FORCED_TEARDOWN).

If the forced_teardown bit is clear, a normal teardown has been initiated. In this case, the BCDMA will do the following:

1. Stops performing any additional fetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/data fetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Channel N Global Configuration Register (<BCHANRT[a]_TRT_CTL> [31] TX_ENABLE).
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sets bit 31 of the BC Flow Reverse Ring Occupancy register to indicate that a teardown has completed.
7. If the current BC reverse ring occupancy is 0, issues an BC reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
8. If the current BC Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
9. If the forced_teardown bit is set, a destructive teardown has been initiated. In this case, the BCDMA will do the following:
   a. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
   b. Completes any packets which have been fetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).

Copyright © 2024 Texas Instruments Incorporated

c. Clears the channel enable in the Channel Global Configuration Register.
d. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
e. Sets bit 31 of the BC Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
f. If the current BC reverse ring occupancy is 0, issues an BC reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively transferring data or not.

The Host determines that a teardown using either of the following methods:

a. Periodically polling the teardown and enable bits for the channel
b. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) for the channel.

Note that the teardown message will actually be written to the next available location in the ring following the last completed packet.

11.1.4.16 BCDMA - Block Copy Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a type 15 TR packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to TR)
   b. Reload Enable to 1 if looping is required, otherwise 0
   c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
   d. Last Entry to TR count minus 1
   e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
   f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Block Copy Queues for the desired BCDMA channel. Channels may provide more than one Queue (1 queue per provided flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/ scheduler implementation.
3. The BCDMA internally provides a level sensitive status signal for the queue which indicates if any work is currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding read channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller sequentially empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. As a TR is read from the descriptor, it is stored in the internal state of the DMA channel until it is completed.
8. All of the data transfers specified in a TR will be completed as a series of reads followed later on by a set of corresponding writes (which may or may not be the same size based on the parameters in the block copy TR).
9. The BCDMA will wait until write status returns for the final write operation that was initiated for each TR. When the final write status is returned within each TR, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which is corresponds.

Copyright © 2024 Texas Instruments Incorporated

10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the BCDMA will increment the reverse occupancy for the channel/flow.
11. After the occupancy is incremented, the BCDMA will indicate the status of the Tx Completion Queue by sending an up event.
12. The Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register (VINT[a]_STATUS_SET) as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
13. The Host responds to the status change from the BCDMA (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. During garbage collection the Host will write to the reverse queue Doorbell register (RINGRT[a]_RT_RDB) for the channel/flow to acknowledge the popping of those completed packets. The doorbell writes eventually cause the queue to become empty.
15. The BCDMA will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register (VINT[a]_STATUS) and potentially de-assert the interrupt line

11.1.4.17 BCDMA - Block Copy Error/Exception Handling

There are 3 specific errors which may be encountered during generic block copy operation and which are trapped by the BCDMA. The following table lists the errors and how the BCDMA will process them:

Table 11-58. BCDMA Generic Block Copy Mode Error / Exception Handling

Condition	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	Selectable(1)	Yes	No	Just that TR	No
Unsupported TR Type	Selectable(1)	Yes	No	Just that TR	No
Bus Errors	Selectable(1)	Yes	Yes	No	Yes

(1) If pause_on_error bit is set in channel configuration

11.1.4.17.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Block Copy engine in the BCDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

11.1.4.17.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Block Copy engine in the BCDMA will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

11.1.4.17.3 Bus Errors

If a bus error is encountered during transmit the BCDMA will log the error by asserting the tx_error bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

11.1.4.18 BCDMA - Split Transmit Channel Setup

This section describes the setup procedure for split Tx channels within the BCDMA. After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by configuring all of the Tx flow entries for the channel and then writing to the Tx Channel Configuration Register A (TCHANRT[a]_TRT_CTL). The Host may choose to write the enable bit in the Tx Channel Configuration Register A (<TCHANRT[a]_TRT_CTL> [31] TX_ENABLE) at

Copyright © 2024 Texas Instruments Incorporated

the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

11.1.4.19 BCDMA - Split Transmit Operation Pause

Setting the pause bit in the Channel N Control Register (<TCHANRT[a]_TRT_CTL> [29] TX_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events.

11.1.4.20 BCDMA - Split Transmit Channel Teardown

This section describes the teardown procedure for split mode Tx channels within the BCDMA. A Tx channel teardown is initiated by the host by writing the tx_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]_TRT_CTL> [30] TX_TEARDOWN). When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the tx_forced_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]_TRT_CTL> [28] TX_FORCED_TEARDOWN) .

If the tx_forced_teardown bit is clear, a normal teardown has been initiated. In this case, the DMA will do the following:

1. Stops performing any additional descriptor fetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR fetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Global Configuration Register (<TCHANRT[a]_TRT_CTL> [31] TX_ENABLE).
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
7. If the current Tx reverse ring occupancy is 0, issues a Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
8. If the current TX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
9. If the tx_forced_teardown bit is set (only valid on BCDMA), a destructive teardown has been initiated. In this case, the BCDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which have been prefetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).
3. Clears the channel enable in the Tx Channel Global Configuration Register (<TCHANRT[a]_TRT_CTL> [31] TX_ENABLE).
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
6. If the current Tx reverse ring occupancy is 0, issues a Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The Host determines that a teardown using either of the following methods:

Copyright © 2024 Texas Instruments Incorporated

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (RINGRT[a]_RT_ROCC) for the channel.

11.1.4.21 BCDMA - Split Transmit Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to TR)
   b. Reload Enable to 1 if looping is required, otherwise 0
   c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
   d. Last Entry to TR count minus 1
   e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
   f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Transmit Queues for the desired BCDMA channel. Channels may provide more than one Queue (1 queue per provided flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/ scheduler implementation.
3. The BCDMA internally provides a level sensitive status signal for the queue which indicates if any work is currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding read channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller sequentially empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. As a TR is read from the descriptor, it is stored in the internal state of the DMA channel until it is completed.
8. All of the data transfers specified in a TR will be completed as a series of reads.
9. The BCDMA will wait until data returns for each read operation that has been initiated. When the final read operation is returned within each TR, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which is corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the BCDMA will increment the reverse occupancy for the channel / flow.
11. After the occupancy is incremented, the BCDMA will indicate the status of the Tx Completion Queue by sending an up event.
12. The Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register (VINT[a]_ENABLE_SET) as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
13. The Host responds to the status change from the BCDMA (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. During garbage collection the Host will write to the reverse queue Doorbell register (RINGRT[a]_RT_RDB) for the channel/flow to acknowledge the popping of those completed packets. The doorbell writes eventually cause the queue to become empty.
15. The BCDMA will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register (VINT[a]_STATUS) and potentially de-assert the interrupt line.

11.1.4.22 BCDMA - Split Transmit Error / Exception Handling

There are 3 specific errors which may be encountered during Tx split operation and which are trapped by the BCDMA. The following table lists the errors and how the BCDMA will process them:

Copyright © 2024 Texas Instruments Incorporated

Table 11-59. BCDMA Tx Error / Exception Handling

Condition	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	Selectable(1)	Yes	No	Just that TR	No
Unsupported TR Type	Selectable(1)	Yes	No	Just that TR	No
Bus Errors	Selectable(1)	Yes	Yes	No	Yes

(1) If pause_on_error bit is set in channel configuration

11.1.4.22.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Block Copy engine in the BCDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

11.1.4.22.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Block Copy engine in the BCDMA will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

11.1.4.22.3 Bus Errors

If a bus error is encountered during transmit the BCDMA will log the error by asserting the tx_error bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

11.1.4.23 BCDMA - Split Receive Channel Setup

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register (<RCHANRT[a]_RRT_CTL > [31] RX_ENABLE) at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

11.1.4.24 BCDMA - Split Receive Channel Pause

Setting the pause bit in the Channel N Control Register (<RCHANRT[a]_RRT_CTL > [29] RX_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events.

11.1.4.25 BCDMA - Split Receive Channel Teardown

An Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408 . This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the BCDMA receives a data phase with the tdown attribute asserted it will immediately set the internal rx_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]_RRT_CTL > [30] RX_TEARDOWN).

Upon seeing the rx_teardown bit asserted the port can perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the rx_forced_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]_RRT_CTL > [28] RX_FORCED_TEARDOWN).

Copyright © 2024 Texas Instruments Incorporated

If the rx_forced_teardown bit is clear, a normal teardown has been initiated. In this case, the BCDMA will do the following:

1. Stops performing any additional prefetches for the channel (TR mode channels)
2. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
3. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]_RRT_CTL > [31] RX_ENABLE).
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
6. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
7. If the current RX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
8. If the rx_forced_teardown bit is set, a destructive teardown has been initiated. In this case, the BCDMA will do the following:

    a. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
    b. Completes any packets which may be pending in the ingress port buffers with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation) . Packets will be drained from the Rx FIFO either using ‘null’ write transfers or real transfers and the Packet Descriptors will be returned with an accurate accounting of actual bytes transferred.
    c. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]_RRT_CTL > [31] RX_ENABLE).
    d. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
    e. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
    f. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the BCDMA. If that is not possible, the host may write the rx_teardown bit directly to a 1.

The Host determines that a teardown using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel’s default flow (first flow in channel) reverse occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) for the channel.

11.1.4.26 BCDMA - Split Receive Operation (TR Packet)

Packet reception in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:

    a. Descriptor Type (set to TR)
    b. Reload Enable to 1 if looping is required, otherwise 0
    c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
    d. Last Entry to TR count minus 1
    e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer

Copyright © 2024 Texas Instruments Incorporated

f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.

2. The Host queues the packet onto one of the Rx TR Queues for the desired BCDMA channel. Channels may provide more than one Rx TR Queue (one per flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller / scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves.
8. All of the data transfers specified in a TR will be completed as a series of writes and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The BCDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which is corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the DMSS will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports / processors / prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard interrupts.

11.1.4.27 BCDMA - Split Receive Error / Exception Handling

Several types of errors/exceptions may be encountered during reception of split Rx data. The following table outlines the various errors and exceptions that can occur:

Table 11-60. Rx Error / Exception Handling

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Descriptor Starvation	All Packet	Exception	No	No	Option	Option	-	No
Protocol Errors	All Packet	Info	No	No	Normal	No	-	No
Drop	Host – normal	Exception	No	No	Partial(1)	Until EOP	-	No
EOP Asserted Late (Long Packet)	BCDMA – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All BCDMA	Error	Selectable(1)	Yes	No	No	Just that TR	No
Unsupported TR Type	All BCDMA	Error	Selectable(1)	Yes	No	No	Just that TR	No

(1) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

Copyright © 2024 Texas Instruments Incorporated

11.1.4.27.1 PKTDMA Exception Conditions

There are a few cases which can occur when processing incoming packets which are not considered errors but which will require handling in order to avoid locking up the PKTDMA engines.

Packet mode channel exceptions include:

- Descriptor Starvation
- Protocol Errors
- Dropped Packets
- Long Packets

11.1.4.27.1.1 Descriptor Starvation

Descriptor starvation occurs when the Port needs to fetch a free descriptor from the RX ring and none are available. When the port detects that descriptor starvation has occurred it will react based on the value of the rx_error_handling bit which was programmed into the Rx Flow N Configuration Register A (<RFLOW[a]_RFA> [28] RX_ERROR_HANDLING).

If the rx_error_handling bit is cleared:

- The Port will increment an internal per-channel starvation counter and will then flush the packet.

If the rx_error_handling bit is set:

- The Port will assert a RX descriptor starvation event (which may cause an interrupt to the Host) and will then wait for the doorbell for the selected flow to be written with a positive value. Note that the intention is that the port will wait for an entry to be added to the ring. It is assumed that when in this mode, if data loss is not desired that the host will guarantee that a chain of buffers will be provided that can receive the entire packet.

11.1.4.27.1.2 Protocol Errors

Protocol errors occur when the port logic detects that the received packet did not pass protocol specific criteria that was checked during reception of the packet. Examples of protocol errors include packet length errors, CRC errors, or alignment errors.

When protocol errors are detected, the port may choose whether or not it will drop the packet. The mechanism that is used to determine which packets to drop and which to forward is application specific. If the port determines that it needs to forward the packet to the Host, it will set the Packet Error bit in the Descriptor indicating that this is a packet which experienced a protocol related error. The type of protocol related error is generally indicated in either the Protocol Specific bits in the Host descriptor or in the Protocol Specific bytes region. The packet length information and certain portions of the Protocol Specific region may not be correct for packets which encounter errors.

11.1.4.27.1.3 Dropped Packets

Packets can be dropped within an Rx Port for any number for reasons which with the exception of the starvation case which was covered above are application specific.

When a Port determines that it needs to drop a packet after reception of the packet has begun, it must flush the remainder of the packet, increment the dropped packets statistic, and rewind any fetched descriptor/buffer chain so that the it can be use the same descriptor/buffer chain on the next packet.

11.1.4.27.1.4 Long Packet

For Rx channels which are not configured in single buffer mode, if the host provides a buffer chain whose total length is insufficient to receive the entire packet, whatever portion of the packet which has not been received will be flushed until an end of packet indicator is received on the PSI-L interface. This behavior will occur regardless of which error handling mode has been selected for the channel.

Copyright © 2024 Texas Instruments Incorporated

11.1.4.27.2 BCDMA Exception Conditions

Since the TR mode engine performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following sections outline these scenarios.

TR mode channel exceptions include:

- Reception of EOL delimiter
- Short Packets
- Long Packets
- Descriptor Starvation

11.1.4.27.2.1 Reception of EOL Delimiter

If an end of line delimiter is received by the Rx (write) side of the BCDMA the EOL_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

11.1.4.27.2.2 EOP Asserted Prematurely (Short Packet)

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

11.1.4.27.2.3 EOP Asserted Late (Long Packets)

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

11.1.4.27.2.4 Descriptor Starvation

Descriptor starvation occurs when the Port receives enough data for a burst but the ring for the channel is currently empty. This causes push back on the receive port and can cause lost data.

The Port will assert a starvation bit in the RX Receive Channel Status register (RCHANRT[a]_RRT_STATUS[1-0]). When the doorbell register (RINGRT[a]_RT_DB) is written to populate the ring the starvation bit will clear. Note that the intention is that the port will wait for an entry to be added to the ring. It is assumed that if data loss is not desired that the host will guarantee that a descriptor is present.

11.2.1 Data Movement Subsystem (DMSS)

This chapter describes the features and functions of the Data Movement Subsystem (DMSS) hardware modules in the device.

11.2.1.1 DMSS Overview

The DMSS module on AM62x provides data movement (DMA) and bridges between the CBA switched interconnect and the packet streaming fabric (network on chip) on the device.

The Data Movement Subsystem (DMSS) consists of DMA/Queue Management components and Peripherals:

- Packet DMA
- Block Copy DMA
- Ring Accelerator
- Packet Streaming Interface (PSILSS)
- Infrastructure components such as CBASS, secure proxy, and an interrupt aggregator

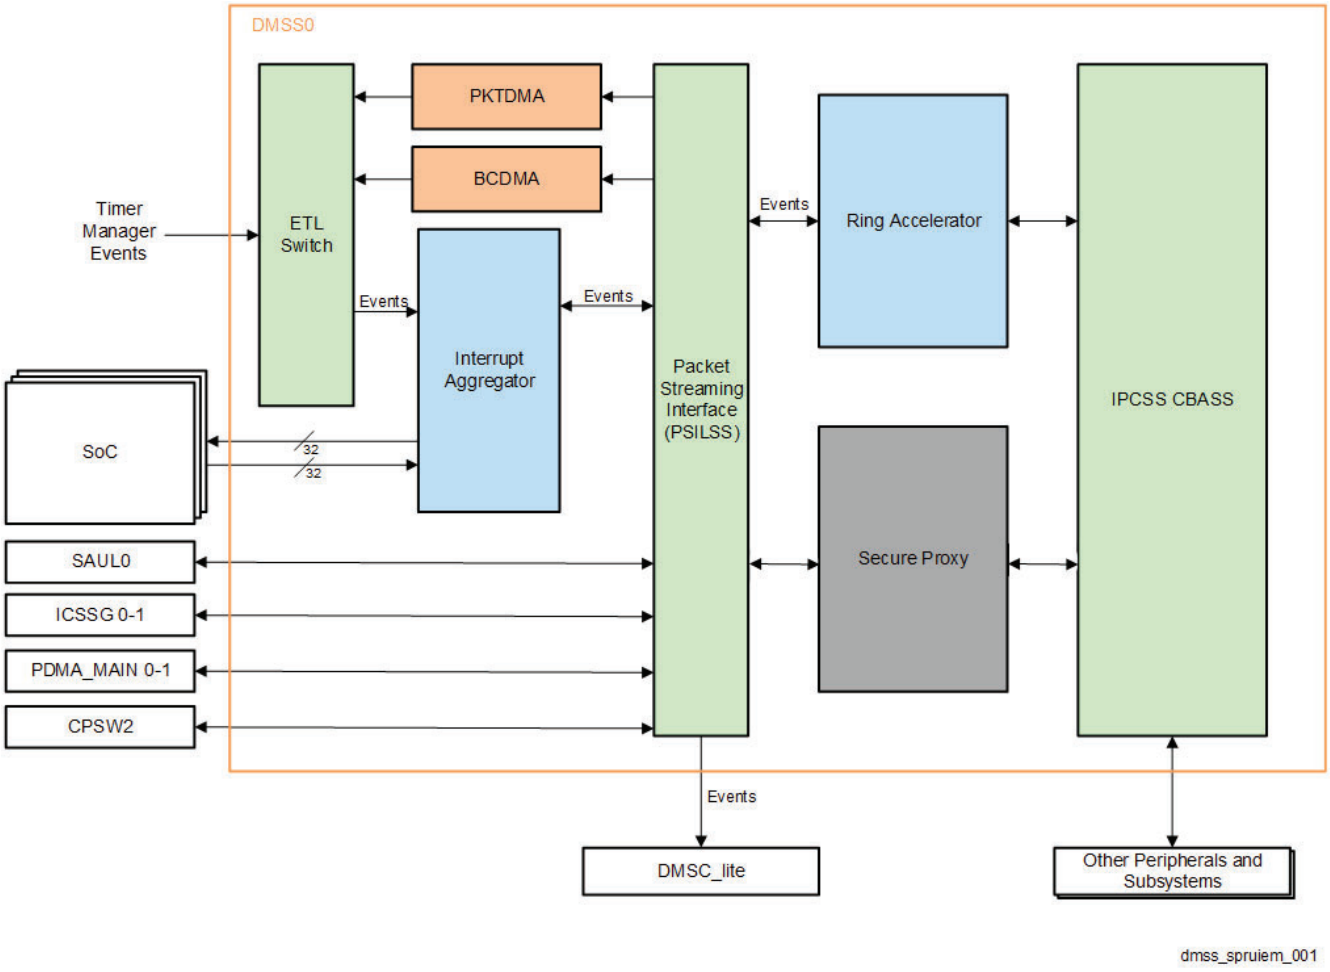

Figure 11-4. DMSS Top-Level Block Diagram

Table 11-61. DMSS Allocation Within Device Domains

Module Instance	Domain	
	MCU	MAIN
DMSS0	-	✓(DMSS)

Note

Some features may not be available. See *Module Integration* for more information.

11.2.1.2 DMSS Functional Description

See Section Chapter 11, DMSS Architecture, for the TI AM62x Data Movement Architecture (DMA) specification.

See the following sections for the respective module description:

- PKTDMA - Section 11.1.1.4
- BCDMA - Section 11.1.1.5
- Ring Accelerator - Section 11.1.1.1
- Infrastructure Components:
  - CBASS - Chapter 3
  - Secure Proxy - Section 11.1.1.2
  - Interrupt Aggregator - Section 11.1.1.3

11.2.1.3 DMSS Interrupt Configuration

This section describes the actions needed to configure interrupts within the DMSS.

Table 11-62. DMSS Parameters

Parameter	Value DMSS	Description
RA_RING_CNT	20	Number of total rings supported (specific to each ring accelerator)
IA_SEVI	1536	Interrupt Aggregator Source Event Input (SEVI) count (specific to each interrupt aggregator)
IS_VINTR	184	Interrupt Aggregator Virtual Interrupt (VINTR) count (specific to each interrupt aggregator)
EO	See Table 10-98, Global Event Map	Event offset

Table *DMSS Software Variables* lists software-configurable variables used in the examples and descriptions.

Table 11-63. DMSS Software Variables

Variable	Valid Range	Description
R#	0 – RA_RING_CNT-1	Ring number
E#	0 – (destination module specific)	Event number
GE#	= EO + E#	Global event number
SB#	0 – IA_SEVI-1	Interrupt aggregator status bit number
VI#	0 – IA_VINTR-1	Virtual interrupt number

11.2.1.3.1 DMSS Event and Interrupt Flow

Figure *DMSS Interrupt Flow* illustrates the event and interrupt flow within the DMSS and output interrupts to a CPU.

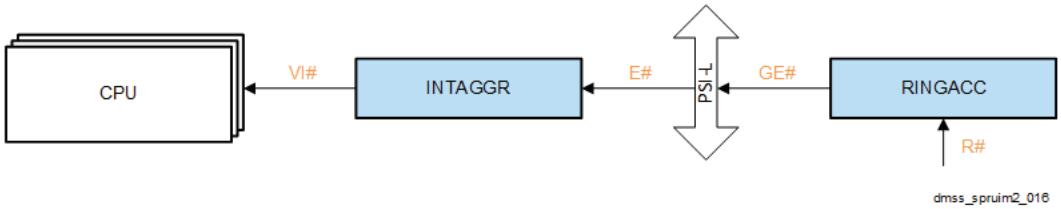

Figure 11-5. DMSS Interrupt Flow

11.2.1.3.1.1 DMSS Interrupt Description

This section describes the interrupt-related information that flows within DMSS and how this information is configured or generated.

1. Ring Number (R#)
   - Data is read from and written to a specific Ring Accelerator ring using direct ring-mode, or secure proxy access
   - The Ring Accelerator has specific ring number ranges for specific purposes. The R# must match the intended purpose of the ring (see Table 10-578, RINGACC Ring Mapping)
2. Global Event and Event Numbers (GE# and E#)
   - GE# = EO + E#
   - EO determines the destination module for the event. The PSILSS will route the GE# to the destination module per the DMSS event mapping, removing EO in the process. The destination module sees only E#. See Global Event Map in *Module Integration* for details.
   - For the INTAGGR module, E# ranges from 0 to (IA_SEVI - 1)
3. Virtual Interrupt (VI#)
   - The INTAGGR maps E# (via software configuration) to any SB#
   - ranges from 0 to (IA_SEVI - 1)
   - Each VI# (0 – (IA_VINTR-1)) is driven by a group of 64 contiguous SB# numbers (VI# driven by SB#'s VI#×64 – (VI#×64)+63)

11.2.2 Ring Accelerator (RINGACC)

This chapter describes the RINGACC module, part of the DMSS.

Note

Not all of the RINGACC Functions specified in the document are supported in the device. Updates will be included in the next revision to reflect only supported modes of operation.

11.2.2.1 RINGACC Overview

The Ring Accelerator (RINGACC or RA) provides hardware acceleration to enable straightforward passing of work between a producer and a consumer.

Table 11-64. RINGACC Allocation Within Device Domains

Module Instance	Domain	
	MCU	MAIN
DMSS0_RINGACC0	-	✓(DMSS)

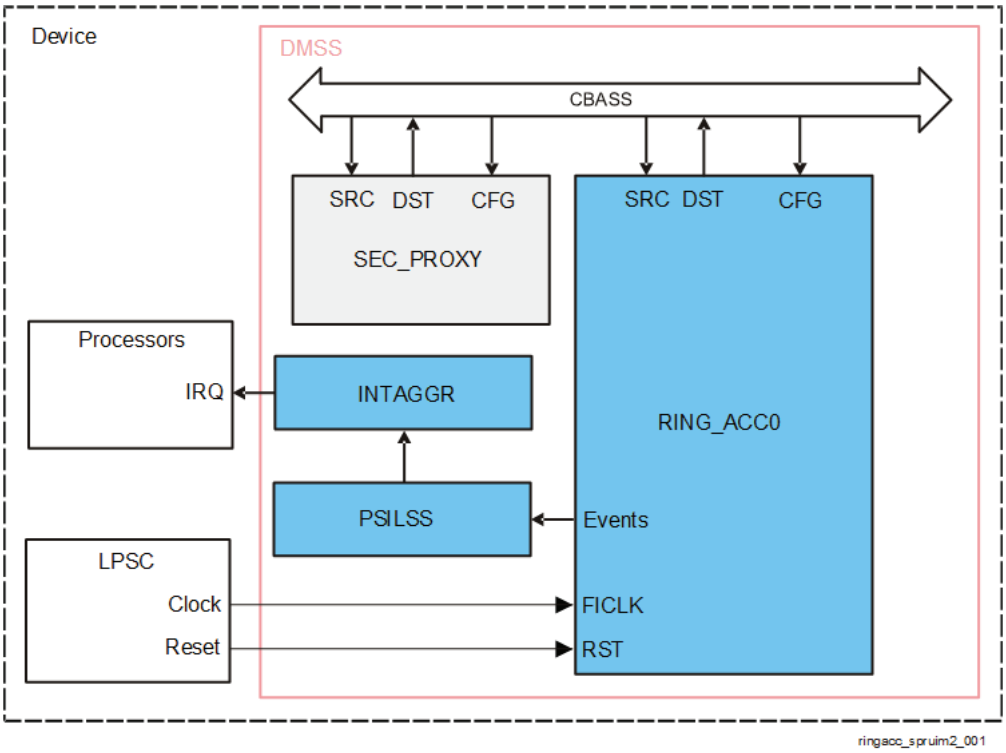

Figure 11-6. RINGACC Overview

11.2.2.1.1 RINGACC Features

- Ring Accelerator implementation
  - Supports up to 32 independent memory mapped ring structure
  - Supports various modes for each ring based on usage and compatibility
  - Provides single word deep shared incoming Transfer Response FIFO
  - Optionally supports dynamic clock gating
  - Provides bit wide source VBUSM read/write target interface for accesses from DMA controller entities
    - Provides 2 word deep command FIFO
    - Provides 2 word deep write data FIFO

Copyright © 2024 Texas Instruments Incorporated

- Provides 2 word deep read data FIFO
- Provides 2 word deep write status FIFO
- Provides bit wide destination VBUSM read/write initiator interface for accesses to ring structures in memory
- Supports up to 16 outstanding writes
- Supports up to 16 outstanding reads
- Provides 2 word deep command FIFO
- Provides 2 word deep write data FIFO
- Provides 2 word deep read data FIFO
- Provides 2 word deep write status FIFO
- Source interface provides an array of 32x512-byte long address windows (four for each ring) which are packed into a single contiguous address range.
  - Read and write addresses which target a specific window are mangled to redirect the read or write transaction to an effective address calculated from the base address for the ring plus current ring offset.
  - Each read or write access presented on VBUSM target interface is modified and bridged onto the VBUSM initiator interface.

Note

Some features may not be available. See *Module Integration* for more information.

11.2.2.1.2 RINGACC Parameters

Table *RINGACC Configuration Parameters* shows the RINGACC configuration parameters in this SoC

Table 11-65. RINGACC Configuration Parameters

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base

11.2.2.2 RINGACC Functional Description

The Ring Accelerator (RINGACC) converts constant-address read and write accesses to equivalent read or write accesses to a circular data structure in memory. The RINGACC eliminates the need for each DMA controller which needs to access ring elements from having to know the current state of the ring (base address, current offset). The DMA controller performs a read or write access to a specific address range (which maps to the source interface on the RINGACC) and the RINGACC replaces the address for the transaction with a new address which corresponds to the head or tail element of the ring (head for reads, tail for writes). Since the RINGACC maintains the state, multiple DMA controllers or channels are allowed to coherently share the same rings as applicable. The RINGACC serves a very similar function to the Queue Manager in the earlier SoCs. The RINGACC uses less memory and is able to place data which is destined towards software into cached memory directly.

11.2.2.2.1 Block Diagram

Figure *Ring Accelerator Block-Diagram* shows ring accelerator's main internal components.

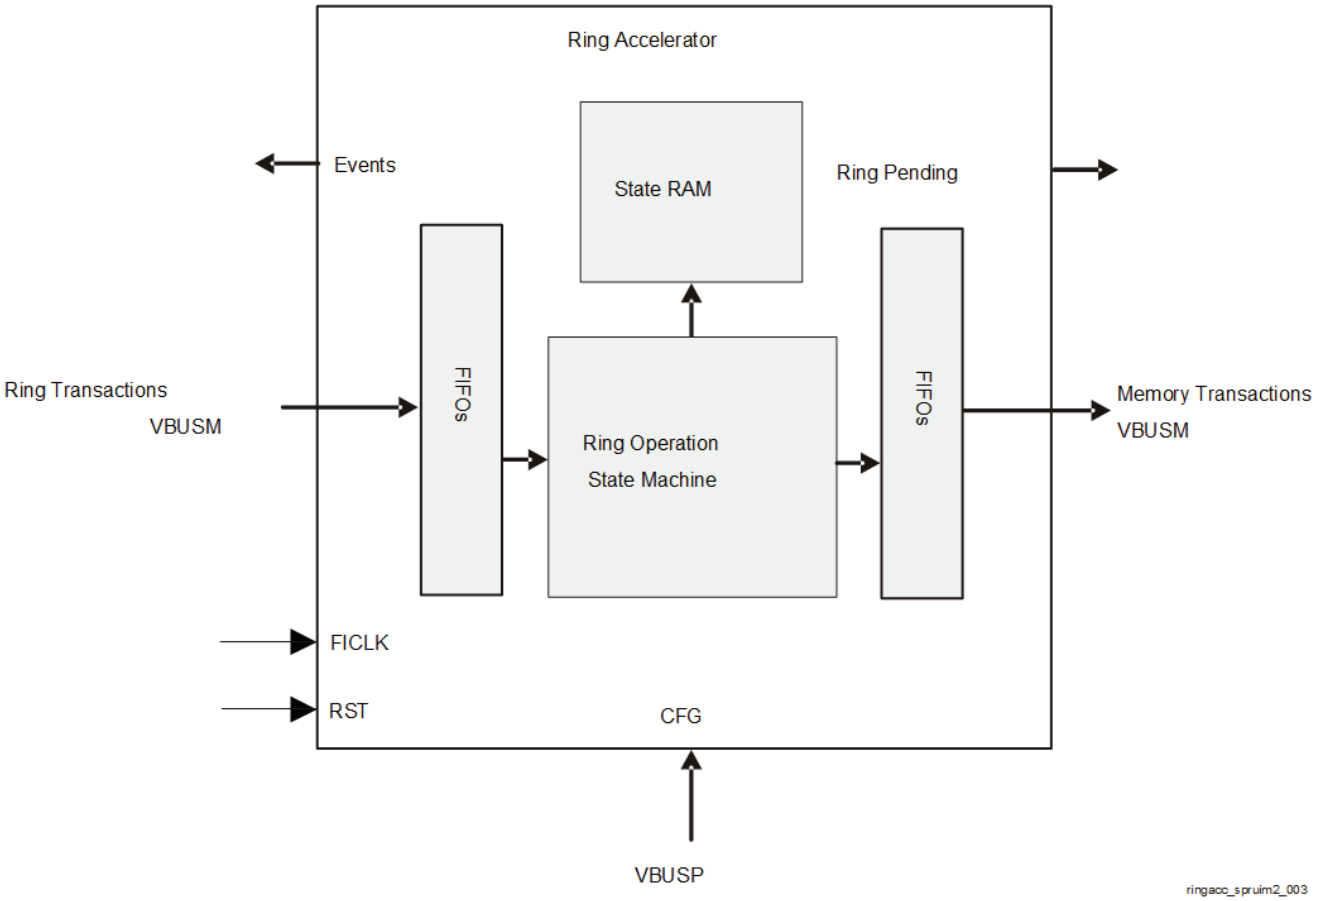

Figure 11-7. Ring Accelerator Block-Diagram

11.2.2.2.1.1 Configuration Registers

The Configuration Registers block is responsible for providing memory mapped registers for configuration of the RINGACC functions. The configuration registers are divided into:

- Static configuration fields , which are typically initialized and then left at specified values for long time periods (or until a reset occurs)
- Real-time (RT) registers , which are modified frequently during runtime. Configuration registers are listed and described in *RINGACC Registers*.

Copyright © 2024 Texas Instruments Incorporated

11.2.2.2.1.2 Source Command FIFO

The Source Command FIFO buffers VBUSM command phases which are accepted from the VBUSM source interface.

11.2.2.2.1.3 Source Write Data FIFO

The Source Write Data FIFO buffers VBUSM write data phases which are accepted from the VBUSM source interface.

11.2.2.2.1.4 Source Read Data FIFO

The Source Read Data FIFO buffers VBUSM read data phases which have been returned from the VBUSM destination interface (via the main state machine) and which are to be output on the VBUSM source interface.

11.2.2.2.1.5 Source Write Status FIFO

The Source Write Status FIFO buffers VBUSM write status data phases which have been returned from the VBUSM destination interface and which are to be output on the VBUSM source interface.

11.2.2.2.1.6 Main State Machine

The Main State Machine (MSM) block implements all of the control logic which is necessary to accept a command from the source interface, perform a lookup into the ring state RAM, determine the effective address for the destination interface transaction, modify the address (and byte count for reads) for the transaction, and place that modified transaction into the outgoing destination FIFOs. The MSM block is also responsible for updating the ring index and occupancy values and for producing output status to indicate changes to the ring state. The MSM also modifies the ring state whenever the read data or write status for a previous ring transaction return and forwards those responses back to the originating initiator.

11.2.2.2.1.7 Destination Command FIFO

The Destination Command FIFO stores VBUSM transaction commands which are output from the MSM as modified versions of transactions that were popped from the Source Command FIFO. The Destination command FIFO allocates a new command ID for each read or write command that is pushed to the FIFO. Read IDs are allocated from a scoreboard maintained in the Destination Read Data FIFO. Write IDs are allocated from a scoreboard maintained in the Destination Write Status FIFO. When a new command is allocated, the Destination Command FIFO also pushes the original cid and crouteid values from the source side transaction into a scoreboard in either the Destination Read Data or Destination Write Status FIFOs depending on the applicable transaction direction. The read interface of the Destination Command FIFO directly drives commands onto the destination VBUSM command interface.

11.2.2.2.1.8 Destination Write Data FIFO

The Destination Write Data FIFO stores write data phases for write commands that are passing through the RINGACC towards memory. The write interface of the Destination Write Data FIFO is directly connected to the read interface of the Source Write Data FIFO and the read interface directly drives write data onto the destination VBUSM write data interface.

11.2.2.2.1.9 Destination Read Data FIFO

The Destination Read Data FIFO provides a read command translation scoreboard and also stores read data phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Read Data FIFO is directly connected to the destination VBUSM read data interface. As read data passes through the Destination Read Data FIFO, the *rid* and *rrouteid* are changed back to their original values using information which was stored in read command translation scoreboard.

11.2.2.2.1.10 Destination Write Status FIFO

The Destination Write Status FIFO provides a write command translation scoreboard and also stores write status phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Writes Status FIFO is directly connected to the destination VBUSM write status interface. As write

Copyright © 2024 Texas Instruments Incorporated

status words pass through the Destination Write Status FIFO, the *sid* and *srouteid* are changed back to their original values using information which was stored in the write command translation scoreboard.

11.2.2.2.2 RINGACC Functional Operation

11.2.2.2.2.1 Queue Modes

Each ring or queue can be in one of four modes that determines how it must be accessed and the compatibility it has with hardware and software.

11.2.2.2.2.1.1 Ring Mode

Ring mode is used when software owns one side of the ring, and hardware or another software owns the other side. This mode allows the software that owns a side of the ring to control that side including accessing the memory directly rather than going through hardware, and software updates the hardware on any changes through the Doorbell registers. These doorbell accesses indicate when software has pushed or popped entries, allowing the entity on the other side of the ring to know when there are elements ready. The ring mode has limitations that the exposed side of the ring is completely under software control, and any atomicity needed must also be performed by software, which is why the exposed side of a ring is usually owned by a single thread of software. This limitation also means that any hardware configuration that would normally access the same ring for both pushes and pops cannot use ring mode as hardware cannot access the exposed side of the ring, such as free queues that are normally read by hardware but could also be pushed by hardware on an error.

When software is popping from the ring, it must guarantee that it never pops more elements through the Doorbell register (RINGRT[a]_RT_DB) than what is valid in the Ring Occupancy (RINGRT[a]_RT_OCC) register, which holds how many elements are ready for software consumption. There could be some elements which have data written to memory but have not received status back from memory and those are not considered ready to pop yet as the ring status has not fully updated. Therefore, just reading from memory to determine the number of elements to pop is not sufficient. If software attempts to pop more than the RINGRT[a]_RT_OCC register value, then the occupancies could go negative resulting in missed down events and spurious interrupts. An optimization for software is to read the RINGRT[a]_RT_OCC register less frequently and keep a local copy which guarantees the maximum number of allowed pops. When the software copy of RINGRT[a]_RT_OCC reaches 0, or periodically, the software can read the register to refresh the value. This must reduce the frequency of register reads instead of reading the register for every software pop.

11.2.2.2.2.1.2 Messaging Mode

Messaging mode requires that all accesses to the queue must go through RINGACC so that all accesses to the memory are controlled and ordered. RINGACC then controls the entire state of the queue, and software has no directly control, such as through doorbells and cannot access the storage memory directly. This is particularly useful when more than one software or hardware entity can be the producer and/or consumer at the same time. Software must access the data through bus accesses to the RINGACC. As with the earlier example, if there are free queues that need the hardware to both push and pop, then they must be configured as at least messaging mode (or a later mode) and not ring mode.

11.2.2.2.2.1.3 Credentials Mode

Credentials mode adds per element credentials storage to messaging mode. This allows multiple producers with their own credentials to have those credentials stored with the element. This allows the consumer to inherit the credentials of each element rather than a single set for the entire queue, such as for DMA TR credential inheritance. This mode requires each operation to use two elements of storage since the credentials are stored in the second element, so the element count must be scaled appropriately. The credentials field is located in the same location as all modes, the word just before the first word of the message.

11.2.2.2.2.1.4 Peek Support

All modes except ring mode allow the peek operations so that software can view the next element without actually popping it from the queue. This is done by reading from a different offset from the normal pop operation. All the same fields are read but the element is not actually popped off of the queue. This is useful for algorithms

Copyright © 2024 Texas Instruments Incorporated

that need to know about the overall queue and head element to make decisions but have not yet decided to pop from the queue.

11.2.2.2.2.1.5 Index Register Operation

In ring mode, the Index (RINGRT[a]_RT_INDX) register follows the software control of the ring through the doorbell registers, while the hardware index (RINGRT[a]_RT_HWINDX) register follows the hardware access of the ring through bus transactions. It works for a ring in either direction as the doorbell register (RINGRT[a]_RT_DB) update indicates whether elements were produced or consumed. But in the other queue modes, there is no simple manner to determine which index is for software or hardware since they both use bus transactions which the module cannot differentiate. So for these other queue modes, the index register is always the read index, and the hardware index register is the write index.

11.2.2.2.2.2 VBUSM Target Ring Operations

Each ring contains four memory spaces on the VBUSM target bus for access, each of which is 512 bytes long, with a total of 4 kB per ring. Each ring space starts immediately after the preceding ring. The allocation per ring is as in Table 11-66.

Table 11-66. Ring Memory Partition

Offset	Operation	Supported Ring Modes
0x0 - 0x1FF	Reads pop from head. Writes push to head.	Read supported in all modes, write supported in all modes except Ring mode
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.	Write supported in all modes, read supported in all modes except Ring mode
0x400 - 0x5FF	Reads peek from head. Writes ignored.	All modes except for Ring mode.
0x600 - 0x7FF	Reads peek from tail. Writes ignored.	All modes except for Ring mode.
0x800 - 0xFFF	Reserved	Reserved

Within each 512-byte (0x200) space, the message data is right justified so that the last byte is always the 511-th byte. The element size of the ring defines which words are valid. The word just before the first valid message word is the credentials field. Access must not be made before the credentials register (CRED[a]_CRED).

11.2.2.2.2.3 VBUSM Initiator Interface Command ID Selection

The RINGACC keeps a transaction command scoreboard for reads and writes. Each scoreboard tracks which command indexes are currently outstanding from the RINGACC and which are free to use. When a read or write is requested by the Main State Machine, the scoreboard corresponding to the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*) for the outgoing transaction on the destination interface. 15 is the maximum index value for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

11.2.2.2.2.4 Ring Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using *ring number*
3. RINGACC calculates effective write address using *ring base* + *ring_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments HW index and HW occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid, cid, and ring number* into scoreboard
7. RINGACC pushes altered *caddress, cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

Copyright © 2024 Texas Instruments Incorporated

At a later time when write status returns:

1. RINGACC recovers original *cid, crouteid,* and *ring number* from scoreboard
2. RINGACC increments SW index and occupancy for ring
3. RINGACC pushes restored *srouteid, sid*, and unaltered write status to output write status FIFO

11.2.2.2.2.5 Ring Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using *ring number*
3. RINGACC calculates effective read address using *ring base* + *ring_index*
4. RINGACC increments HW index and decrements HW occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress, cid* and unaltered remainder of command attributes to output FIFO (note routeid is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid, crouteid*, and *ring number* from scoreboard
2. RINGACC increments SW index and decrements SW occupancy for ring
3. RINGACC pushes restored *rrouteid, rid,* and unaltered read data, status, and other control signals to output read FIFO

11.2.2.2.2.6 Host Doorbell Access

The following sequence will occur for each VBUSP write to the doorbell register (RINGRT[a]_RT_DB) for a ring:

1. RINGACC extracts ring number from config address
2. RINGACC looks up ring state using ring number
3. RINGACC adds doorbell ring value to both HW and SW occupancies for ring
4. RINGACC re-evaluates pending bit for ring

11.2.2.2.2.7 Queue Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using *ring number*
3. RINGACC calculates effective write address using *ring base* + *ring_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments WR index and RD and WR occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid, cid*, and *ring number* into scoreboard
7. RINGACC pushes altered *caddress, cid* and unaltered remainder of command attributes to output FIFO (note routeid is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid, crouteid*, and ring number from scoreboard
2. RA pushes restored srouteid, sid, and unaltered write status to output write status FIFO

11.2.2.2.2.8 Queue Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

- RINGACC extracts ring # from incoming read transaction address
- RINGACC looks up ring state using *ring number*
- RINGACC calculates effective read address using *ring base* + *ring_index*
- RINGACC increments RD index and decrements RD and WR occupancy for ring
- RINGACC re-evaluates pending bit for ring
- RINGACC munges cid to add indicator in 4 MSBs to reconstitute routeid for returning read data

Copyright © 2024 Texas Instruments Incorporated

- RINGACC pushes altered *caddress, cid* and unaltered remainder of command attributes to output FIFO (note routeid is not included)

1. At a later time when read data returns:

- RINGACC recovers original *cid, crouteid*, and *ring number* from scoreboard
- RINGACC pushes restored *rrouteid, rid*, and unaltered read data, status, and other control signals to output read FIFO

11.2.2.2.2.9 Mismatched Element Size Handling

When less data is written than defined by the element size for the ring for RING or MESSAGE modes, only the written data is stored in the memory and any remaining bytes maintain their old values. The index and occ are still incremented normally, and any special fields that are unwritten are assumed to be 0 (such as the length for QM mode rings).

Writing less data for CREDENTIALS mode is illegal, as those types need the full data to append the additional words to the correct offsets in memory.

When more data is written than defined by the element size for the ring, it will be an error and the write will be ignored and no index or occ increments occur. The only exception is for writes to an 8 byte element size ring, where the additional fields up to another 8 bytes are allowed but not written (for old Queue Manager compatibility).

When less data is read than defined by the element size for the ring, only the read data is fetched from memory, and any remaining bytes are lost. The index and occ are still incremented normally.

When more data is read than defined by the element size for the ring, it will be an error and the read will not affect the ring, the read data will be 0s, and no index or occ decrements occur. Access beyond the credentials word should not be attempted and can result in unpredictable behavior.

All accesses must be for multiples of 32 bit words, and partial bytes are not supported for all ring modes.

11.2.2.2.3 Events

The module outputs events about queue levels that can be used by an external module for statistics or interrupts.

Each queue has:

- an up event when the queue goes from 0 elements to 1 or more elements
- and a down event when the queue goes from 1 or more elements to 0 elements. The event number is programmable per queue in the RING[a]_EVT register. This event occurs when the state machine updates the final occupancy for the queue. In ring mode this is when the response from the memory access returns, while in other queue modes this is when the operation is processed.

An event number programmed to 0xFFFF indicates to not produce an event for that ring when an event is not necessary. The register event number fields reset to 0xFFFF, so they must be programmed to a valid value before events will be generated. This applies to the monitor event number fields as well.

11.2.2.2.4 Bus Error Handling

If a bus error is detected on a response to a ring memory transaction, an error event is triggered to alert software. Since the ring contents may be corrupted as the push or pop was not completed correctly, software should consider resetting the ring and any software or hardware elements using the ring. A log register (RINGACC_ERROR_LOG) captures the ring that had the error and whether it was from a push or pop, and an error up event is sent to the programmed event number. After an error is logged, another will not be captured until the first is read out. When read, if an error is pending an error down event is sent to clear any interrupt, and then the next bus error log can be captured. A read of the RINGACC_ERROR_LOG register when there is no error log pending will not produce any down events. The event that is triggered is also programmable. Only

Copyright © 2024 Texas Instruments Incorporated

legal push and pop operations will capture this error, and not for any peek, emudbg read, flush command, or any operations that is illegal and causes the resulting memory access to be flushed.

11.2.2.2.5 Monitors

Monitors can be configured that allow various functions to be tracked of programmed queues. Each monitor is programmed to monitor a particular queue, the function to provide, and the data source to operate on. The supported functions are: to check the queue against programmed thresholds, to keep track of watermarks of the queue, to keep track of starvation occurrences (a read of an empty queue), or statistics capture. The supported data sources are: the queue element count, the head element size value, or the accumulated size value. Each monitor can also be programmed to produce an event should it have a triggering condition.

11.2.2.2.5.1 Threshold Monitor

A threshold monitor uses a programmed low threshold value and a programmed high threshold value to track the data source in the queue and cause an interrupt or status when a threshold is broken, either below the low value or above the high value. This is useful for software to replenish empty buffers when a queue has too few, or for a queue to accumulate enough elements so that software must start processing them, or for debug. The threshold being broken will cause the up or down event.

11.2.2.2.5.2 Watermark Monitor

A watermark monitor tracks the low and high values of the data source since the last read of the monitor. After initial setup or clearing, the watermark values will load the current value of the data source as the low and high. Then for successive operations if the resulting data source of the queue is below the low watermark, or above the high watermark, the associated watermark will be updated. When the monitor value registers are read, the value is cleared and starts tracking again using the current data source value. This can be useful for tracking low and high values of queue element counts or sizes for data tracking, debug or future optimizations, such as allocating items to a queue or buffer sizes based on counts.

11.2.2.2.5.3 Starvation Monitor

A starvation monitor tracks the number of starvation events (a read to an empty queue) that occurred on the queue. The data source is ignored, and the starvation count is always incremented whenever there is a read to the queue and the queue is empty. The count is cleared when the monitor value is read. This can be useful to trigger if any starvation event occurs, or to track how many of these events occur in a timeframe, and can be used for future optimizations or debug.

11.2.2.2.5.4 Statistics Monitor

The statistics monitor can track some simple statistics on the queue operations. The data source is ignored. The first value is the count of the number of writes to the queue, and the second value is the count of the number of reads from the queue. The counts are cleared when the monitor values are read. This can be useful to track the activity on a queue, and can be used for future optimizations or debug.

11.2.2.2.5.5 Overflow

RINGACC provides an overflow function where a push to a full ring will result in a push to a special overflow ring, rather than just losing the pushed data. The overflow ring is defined through RINGACC_OVERFLOW register, and that ring must be defined with a large enough element size to cover the element size of any other ring, as well as enough elements to hold enough overflow data (as an overflow to the overflow ring will be lost). When there is a push to a full ring, there will be two elements written to the overflow ring, first the push data, and then the ring number that was full. A supervisor entity can own the overflow ring and perform what actions are needed from the overflow data. The size of the overflow ring must be an even number since two elements will be pushed for each overflow event. The overflow ring must be configured in ring or message modes.

An overflow queue value of 0xFFFF will disable the overflow function and will not record queue overflows. (SR2.0)

Copyright © 2024 Texas Instruments Incorporated

11.2.2.2.5.6 Ring Update Port

To enhance performance for DMAs, the RINGACC provides a bus that indicates when ring updates occur, allowing the DMA to track their own rings and detect updates before the responses arrive. The bus will go valid whenever there is an update to the state of a ring, which can be from a push, pop, or doorbell write. It will not go valid for a peek, an emudbg pop, or a push to a full ring, as those do not update the ring state. When the bus is valid, the other signals are valid and indicate whether the operation was a push or a pop, whether the resulting state of the ring is empty, the ring number, and the number of elements updated to the ring (the push determines whether it is subtracted or added to the current count). One special case is a pop from an empty ring, which indicates an update but the element count is 0 since no items were actually popped, but a DMA using the cnt to add or subtract must handle this correctly by default. The bus will go valid once the operation command has been completed, and not after the response has been receivied, even for ring mode rings, allowing the DMA to see the update as soon as it is known by the RINGACC even before it is known to software.

11.2.2.2.5.7 Tracing

This module provides a trace output of all operations so that the traffic can be viewed at a later time. The trace uses a simple write-only 32-bit VBUSP bus, with a defined packet header. The msgtype field defines the type of operation, and the message data is simply the data involved in the operation. It is likely the trace output will be read slower than new operations could provide data, so there will be a trace buffer able to hold two complete messages plus trace headers. If a new operation starts while the trace buffer does not have enough space, then that trace message will not be sent. And RINGACC_TRACE_CTL register controls whether to enable the trace output, whether to trace a single queue or all queues, and whether to include the message data in the trace output.

Table 11-67 shows the trace message for a push.

Table 11-67. Trace Message for a Push

11.2.3 Secure Proxy (SEC_PROXY)

This chapter describes the Secure Proxy (SEC_PROXY) module in the DMSS.

11.2.3.1 Secure Proxy Overview

The Secure Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses.

11.2.3.1.1 Secure Proxy Features

Secure Proxy supports the following features:

- Provides proxy function to store large data bursts that a host can only access in smaller amounts
- Supports a configurable number of threads, where each has their own independent proxy function
- Keeps the large data burst coherent until the complete data has been accessed
- Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
- Supports a configurable target resource. The target has a configurable number of channels, size of each channel and base address
- Supports a programmable fixed queue for each proxy thread
- Supports multiple producers all writing to the same queue
- Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Supports programmable thresholds for when to generate events
- Optionally supports dynamic clock gating

Table 11-70. Secure Proxy Allocation Within Device Domains

Module Instance	Domain	
	MCU	MAIN
DMSS0_SEC_PROXY0	-	✓(DMSS)

11.2.3.1.2 Secure Proxy Parameters

Table *Secure Proxy Configuration Parameters* shows the Secure Proxy configuration parameters set during SoC design.

Table 11-71. Secure Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies(1)	Message Size(2)	Target	Channels(3)	Sizes(4)
DMSS0_SEC_PROXY0	76	64	DMSS0_RINGACC	20	4096

(1) Number of proxy threads supported. Can be read off from the SEC_PROXY_CONFIG read-only register
(2) Number of bytes for message. Can be read off from the SEC_PROXY_CONFIG read-only register
(3) Number of channels for the target
(4) Number of bytes per channel supported for the target

Note

Some features may not be available. See *Module Integration* for more information.

11.2.3.2 Secure Proxy Functional Description

This module provides proxy functions for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are:

- large messages (for power control, security control, or IPC)
- data descriptors that are more than a pointer
- DMA Transfer Requests (TR)

All of these require larger data sets, from 12 to 128 bytes, and the storage hardware requires the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as registers, and the largest CPU access is typically 8 bytes. So the proxy provides the ability to access the hardware with a single burst, and at the same time allows the CPU to access the same data in smaller accesses. The proxy itself does not contain the resources, but will front other hardware that do contain the resources. The proxy will access this other hardware with the entire data in a single burst, once the host has completed the data.

Figure *Secure Proxy Block Diagram* describes Secure Proxy major building block

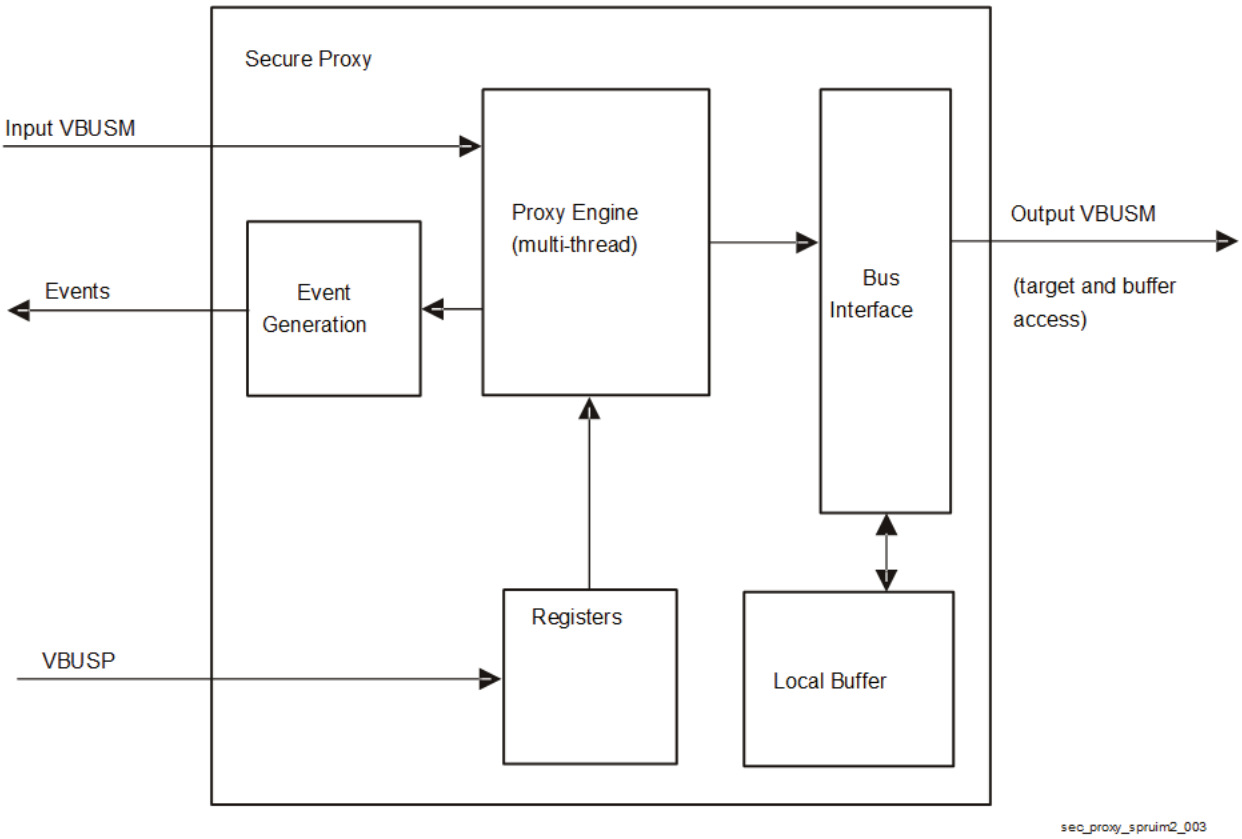

Figure 11-8. Secure Proxy Block Diagram

11.2.3.2.1 Targets

11.2.3.2.1.1 Ring Accelerator

The RINGACC provides four distinct offsets to use per ring/queue shown in Table *RINGACC Offset per Ring/Queue*, totaling 4 KB space per ring/queue.

Secure Proxy always writes to tail, which is the offsets from 0x200 to 0x3FF. Secure Proxy always reads from the head, which is the offsets from 0x000 to 0x1FF. The latter two offsets in RINGACC are not used by this proxy. And if the proxy message size is less than 512 bytes, then it always accesses the upper bytes of those regions, so that the message always ends on the last byte of each region, byte 511.

Copyright © 2024 Texas Instruments Incorporated

Table 11-72. RINGACC Offsets per Ring/Queue

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored.
0x600 - 0x7FF	Reads peek from tail. Writes ignored.
0x800 - 0xFFF	Reserved.

This means that target writes will use the following calculation:

target base address + (queue × 4KB) + 0x400 - msg_size (17), and burst until offset 0x3FF.

And target reads will use the following calculation:

target base address + (queue × 4KB) + 0x200 - msg_size (18), and burst until offset 0x1FF.

11.2.3.2.2 Buffers

The proxy does not store all the buffers internally. It is programmed with a buffer base address (SEC_PROXY_BUFFER_L, SEC_PROXY_BUFFER_H), and all accesses to the buffer are made through the output VBUSM port using that base. The external buffer must be enough to store one msg_size per proxy thread. The proxy only includes a small temporary buffer to save one entire message when accessing the target. Otherwise all host accesses are made to the external buffer. This buffer storage must be considered private for the proxy hardware, so any other access can cause unpredictable results.

11.2.3.2.3 Proxy Credits

To support outbound proxy limits, the proxy will use internal credits for tracking resource usage. SEC_PROXY_THREAD[a]_CTL register sets the max credits each outbound proxy thread contains. When a proxy thread sends a message, the current credit count (SEC_PROXY_THREAD[a]_STATUS) decrements by 1. If the current credit count is 0, then the proxy thread is not allowed to send any more messages, and they just remain inside the proxy (so that the host can come back later when a credit has become available and quickly send the same message). When a message that was send by this proxy thread is read by an inbound proxy thread then the credit is returned to this proxy thread and the current credit count increments by 1.

For inbound proxy threads, the credits are used to track pending messages. When an outbound proxy thread sends a message that is read by this proxy thread, then the current credit count of this proxy thread is incremented by 1. A current credit count that is non zero indicates a message is pending and can be read. When the proxy thread completes the read of a message the current credit count is decremented by 1. If the current credit count is zero, then the proxy thread will read an empty message where all the data is 0s. The credit count saturates at 255, so if there can be more messages in the system for that proxy thread than 255 then multiple proxy threads should be used, or the count can become mismatched after a saturate.

11.2.3.2.4 Proxy Private Word

To support tracking of credits from each proxy thread, the proxy will extract the first word from the total message size for private tracking usage. This will include saving the proxy thread ID used within the proxy. This is necessary so that when a proxy reads a new message from the target it can inspect this word and return the credit to the source proxy thread. This allows the outbound proxy threads to have a set number of message credits, which decrement when a new message is written, and increment when a message from that proxy thread is read, thus keeping the credits in the system coherent. Any data written to this first word of the message will be ignored, so software should not write to the first word of messages through the proxy. Consumer software can use the first word to identify the source proxy thread of the message (SEC_PROXY_DATA_j).

Copyright © 2024 Texas Instruments Incorporated

11.2.3.2.5 Completion Byte

The proxy completes a message when the completion byte is accessed. This completion byte is the final byte in the full size of the message. This byte can be written by any size access, whether byte, 32-bit, or 64-bit word. The write of a message is not complete until this final byte of the message is written, and only then will the message be sent to the target. The read of a message is not complete until this final byte of the message is read by the host, and only then will reading a new message be allowed. Even if the final byte of the message is not needed, it must be accessed to complete the message inside the proxy hardware.

11.2.3.2.6 Proxy Thread Sizes

There are a configurable number of proxy threads in the module. Each thread has its own address space to the module and determining which proxy thread is being accessed is simply based on the address bits above the final size of each proxy thread space. Since each proxy thread will be programmed to a single resource, the only space requirement is that for using 4 KB to match typically used MMU page sizes. Only the first N bytes, matching the target channel size, is usable.

11.2.3.2.7 Proxy Thread Interleaving

Each proxy thread must have a single owner, as each proxy thread only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy thread. Then they will have their own buffer and each can access a different resource at the same time. Each proxy thread is completely independent and kept coherent regardless of accesses to other proxy threads or regardless of the order of accesses. So the proxy support interleaving of multiple hosts' accesses.

11.2.3.2.8 Proxy States

Each proxy thread uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy thread is in use or not, but also for error detection. The proxy thread always starts in idle state, when there is no currently activity. There is a write state for when the proxy thread has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy thread has read data from a resource and that entire data has not been fully read by the host. When a proxy thread access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

11.2.3.2.9 Proxy Host Access

A proxy thread begins in an idle state, where there is no data in the buffer. In this state the proxy thread will accept an access to the resource.

11.2.3.2.10 Proxy Host Writes

The first write to an idle proxy thread puts the proxy thread into write mode for the selected channel. Further legal writes are stored in the buffer for the enabled bytes and offset within the buffer. A write to a previously written location will overwrite the previous data. The buffer is not cleared initially, so if a byte is not written, the message will include previous buffer data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy thread is then put back into idle state. A write completion when there are no credits available results in the message not being written to the resource and the proxy thread remains in write mode (so that the message can be quickly completed when a credit becomes available).

11.2.3.2.11 Proxy Host Reads

When in idle state, the first read to the proxy thread will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy thread is put back into idle state. If an initial read is made and there are no pending messages, the proxy thread will return an empty message, where the data is all 0s.

Copyright © 2024 Texas Instruments Incorporated

11.2.3.2.12 Buffer Accesses

Each read or write will actually trigger a read or write to the external buffer space allocated for that proxy thread, where the real message data is stored. In addition, when a write message completes, the external buffer will be read for the entire message for that proxy thread so that it can then be written to the target. Similarly, after a read causes a read from the target to get a new message, the entire message is written to the external buffer to store the message to the buffer.

11.2.3.2.13 Target Access

After the write has completed and the external buffer read for the entire message, the entire message is then written to the target as a single burst. Similarly, for a read that needs a new message, the target is read for a full message as a single burst.

11.2.3.2.14 Error State

If an error is detected in a proxy thread, the proxy will put that proxy thread into error state, and the current buffer will be lost. A status bit will be set that indicates the proxy thread is in error. All accesses to that proxy thread will be ignored until the status bit is cleared. Once cleared the proxy thread is put back into idle state. Errors are an access to an offset beyond the length of the message, or a mismatch in the direction of access against what was programmed such as reading an outbound thread or writing an inbound thread.

11.2.3.2.15 Permission Inheritance

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target.

11.2.3.2.16 Resource Association

Each proxy thread has a register (SEC_PROXY_THREAD[a]_CTL) to define the resource within the target that the proxy thread is mapped to. The host has no ability to access any other resource in the target. This allows the setup of the proxy to determine the resources that all the hosts use.

11.2.3.2.17 Direction

Each proxy thread has a register (SEC_PROXY_THREAD[a]_CTL) to define the direction for access. It can either be an outbound proxy thread for writing messages to resources. Or it can be an inbound proxy thread for reading messages from resources. The host must match the direction programmed or it will result in a proxy thread error.

11.2.3.2.18 Threshold Events

Each proxy thread can produce events based on the state of the resource it uses. For outbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to write. For inbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to read. These threshold values are programmed in SEC_PROXY_EVT_MAP_j, allowing the host to determine how often it gets events. Programming the count values while the threshold is set to 0 will not trigger events, but if the threshold is not 0 then programming the counts will trigger events based on whether the threshold is reached or not. No event is generated if the event is programmed to 0xFFFF.

11.2.3.2.19 Error Events

Each proxy thread can produce an event when it has detected an error. This error occurs when the host violates the programmed setup of the proxy thread or accesses beyond the message size. There is a separate status bit per proxy thread for these errors. No event is generated if the event is programmed to 0xFFFF.

11.2.3.2.20 Bus Error and Credits

If a target read for a message returns a bus error, this indicates the read was bad and the data is corrupt and usually 0s. Because the private word in contained in the message, if the private word is corrupted then the source proxy thread is not valid and the credit return will not be correct. Since the data is usually 0, this means the credit would be returned to proxy thread 0 incorrectly most of the time. And the credit will be lost for the

Copyright © 2024 Texas Instruments Incorporated

actual source proxy thread of the message that was not read correctly. The hardware has no way to correct for this, as the message from the target is corrupt so it does not know the correct owner of the credit. If software detects that a read message is corrupt, it can attempt to correct the situation by resetting the affected proxy threads using that queue, to restore their credit counts back to the default. Software may also want to reset proxy thread 0 since it may be getting extra credits.

11.2.3.2.21 Debug

When the transaction has the emudbg set for a read, all side effects will not occur. This means that the read will not cause a target read since that would affect the target, and instead current buffer will be read even if the previous message has completed.

Copyright © 2024 Texas Instruments Incorporated

11.2.4 Interrupt Aggregator (INTAGGR)

This chapter describes the INTAGGR module, part of DMSS

11.2.4.1 INTAGGR Overview

The Interrupt Aggregator (INTAGGR or INTA) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane (ETL) bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

Table 11-73. INTAGGR Allocation Within Device Domains

Module Instance	Parameters	
	MCU	MAIN
DMSS0_INTAGGR0	-	✓(DMSS)

11.2.4.1.1 INTAGGR Features

The DMSS0_INTAGGR0 supports the following features:

- 64-bit VBUSP target using 64-bit registers
- Provides a set of TI Interrupt Architecture compliant interrupt status and mask register sets which are used to pass specific event status to one or more Host blocks.
  - Maps a collection of DMA Messaged Events which are input through an Event Transport Lane into specific bit locations in one or more interrupt cause registers
  - Mapping is performed based on a programmable table which provides a single location for each ordinal input event number (0 through sevt_cnt-1)
    - Table specifies a specific bit in a specific cause register that the event should set or clear depending on the type of event (up vs down)
    - Tracks a single 'event up' / 'event down' condition. There is no event counting. (The 'cnt' field of the ETL is ignored.)
  - Tracked status interrupts are presented to the user through a standard interrupt register interface.
    - Provides separate 'enable set' and 'enable clear' registers.
    - Provides both masked and unmasked interrupt status.
    - Interrupt status bits can be manually cleared using 'write 1 to clear'.
- Provides an optional set of Unmapped Event (UNMAP) which can take an 'unmapped' event from the ingress ETL and generate a Global event on the egress Event Transport Lane (ETL) interface.
  - Each ingress event can generate an egress Global event on the egress ETL, controllable through a mapping register.
  - Each mapping register has the option of alternatively directly setting an interrupt status bit.
- Provides an optional set of Global Event Input (GEVI) counters which can count events which were delivered via an ingress Event Transport Lane (ETL).
  - Each counted event provides an MMR by which the count can be read and an MMR by which a specified amount can be decremented by the host.
  - Each counted event generates an egress Global event on a zero to non-zero and non-zero to zero transition, controllable through a mapping register.
  - Each mapping register has the option of alternatively directly setting an interrupt status bit.
- Provides an optional set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on the egress ETL interface.
  - Each mapping register has the option of alternatively directly setting an interrupt status bit.

Copyright © 2024 Texas Instruments Incorporated

- Provides an optional set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL.
  - Each ingress event index provides a configurable 'pulse' or 'rising edge' bit, plus the configurable index of the generated Global event.
- Supports dynamic clock gating via

Note

Some features may not be available. See *Module Integration* for more information.

11.2.4.1.2 INTAGGR Parameters

Table *Interrupt Aggregators Parameters* shows the Interrupt Aggregator 0, parameters set during design time.

Table 11-74. Interrupt Aggregators Parameters

Module Instance	Parameters				
	VINTR[1]	SEVI[2]	GEVI[3]	LEVI[4]	MEVI[5]
DMSS0_INTAGGR0	184	1536	256	32	128

(1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs. Value can be read from INTAGGR_INTCAP register.

(2) SEVI – Number of Main (Steerable) Events. Value can be read from INTAGGR_INTCAP register.

(3) GEVI – Number of Countable Events. Value can be read from INTAGGR_AUXCAP register.

(4) LEVI – Number of Local Event inputs. Value can be read from INTAGGR_AUXCAP register.

(5) MEVI – Number of Multicast Events. Value can be read from INTAGGR_AUXCAP register.

11.2.4.2 INTAGGR Functional Description

The Interrupt Aggregator (INTAGGR) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the Host(s) in the system. Both the signaling and content of TI system events are incompatible with standard interrupt controllers. The INTAGGR provides mechanisms which convert the TI proprietary system events to standard level sensitive pending bits which can be used by all downstream interrupt infrastructure. Events can be presented to the INTAGGR in two different forms:

- Events may be active high pulses, or clock synchronous rising edges, which are input on separate orthogonal pins. These are called 'Local Events'.
  - Local event signals that are used in pulse counting mode must be sourced by the same clock as the interrupt aggregator.
  - Local event signals that are used in edge counting mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the interrupt aggregator clock, and they must remain high for at least 1 'slow' clock cycle.
- Events may be messages which are input in time division multiplexed sequential order from an Event Transport Lane. These are called 'Global Events'.

In both cases, these events need to be conditioned to transition them from a transient indicator that something occurred to a persistent and reliable indication of the current state of the system. The IA is architected to perform this conversion in an efficient and cost effective manner.

11.2.4.2.1 Submodule Descriptions

11.2.4.2.1.1 Status/Mask Registers

The Status and Mask Registers block is responsible for providing persistent storage for the interrupt status and mask bits and for formatting those in a way that is compliant to the TI Interrupt Architecture requirements. These requirements include the ability to set and clear bits orthogonally and to provide a masked version of the status register that corresponds to the supplied bit mask for each register.

11.2.4.2.1.2 Interrupt Mapping Block

The Interrupt Mapping Block accepts ordinally numbered events (0-N) and converts those ordinal event numbers into a status register number and bit number pair that is then used to manipulate the specified bit in the Status Registers block.

11.2.4.2.1.3 Global Event Input (GEVI) Counters

The GEVI Counters block is responsible for accepting an Event Transport Lane events and summing the total message counts for each received event index. The module creates global egress events for zero to non-zero count up' events and non-zero to zero 'count down' events. The egress global event index is configured via GEVI[a]_MCMAP register, so count status egress events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

11.2.4.2.1.4 Local Event Input (LEVI) to Global Event Conversion

The Local to Global event block is responsible for accepting an array of input pins and independently counting the number of cycles for which those pins are asserted high, or by counting individual clock synchronous rising edge events. The counting mode is configurable on a 'per pin' basis. The events are converted to egress Global events on an egress ETL. Global events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

11.2.4.2.1.5 Global Event Multicast

The Global event multicast block takes an ingress global event from an ingress ETL, and maps it into two egress Global events on two egress ETL interfaces. Global events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

11.2.4.2.2 General Functionality

Copyright © 2024 Texas Instruments Incorporated

11.2.4.2.2.1 Event to Interrupt Bit Steering

Each time an event message is received on the Main Event Transport Lane interface, the interrupt mapping block performs a direct lookup into an SRAM using the event number as the address. The SRAM stores a corresponding interrupt status (INTR_STATUSM) register and bit number within that register (VINT[a]_STATUS_MSKD) which are to be manipulated anytime a message is received indicating something occurred on that specific event. When an up event is received, the specified bit in the [a] Status register will be set. When a down event is received, that same bit will be cleared. This block is what allows flexible aggregation of various system events into an array of bits in the interrupt status registers. It is intended that this mapping is essentially static - set up when a resource is allocated and left untouched until the resource is no longer needed. Note that the 'cnt' field of the ETL is ignored and no interrupt counting is performed here. When 'UpDn=1', the interrupt flag bit is set, and when 'UpDn=0', the flag bit is cleared.

11.2.4.2.2.2 Interrupt Status

The event messages which are generated from the event to interrupt bit steering logic are input to the Interrupt Status registers. Each time an event is received, the interrupt status registers machine will assert or de-assert the specified bit in the specified register. The assertion and de-assertion in the interrupt status register is unaffected by the interrupt enable state. When an up event is received, the corresponding bit is set and when a down event is received, the corresponding bit is cleared. Some sources of input events will not include the ability to send a down event. In these cases, the interrupt router provides the ability to clear the status bits through the Interrupt Source Clear register (VINT[a]_STATUS). The host will write a one to the specific bit in the register which is to be cleared and the interrupt status machine will clear the bit internally. It is not intended that the Host directly clear bits which are automatically cleared via down events from the source itself.

11.2.4.2.2.3 Interrupt Masked Status

Interrupt enable bits are used in conjunction with the interrupt status bits to create the interrupt masked status register values. The interrupt masked status register (VINT[a]_STATUS_MSKD) contains the value of the interrupt status ANDed with the value of the interrupt enable register (VINT[a]_ENABLE_SET). Each time a new event message is received from the event to interrupt bit steering logic or the interrupt enable register is modified, the interrupt masked status register is re-evaluated.

11.2.4.2.2.4 Enabling/Disabling Individual Interrupt Source Bits

Separate (VINT[a]_ENABLE_SET and VINT[a]_ENABLE_CLR) registers are provided to allow individual enable bits to be enabled or disabled without the need for a read-modify-write operation. When the VINT[a]_ENABLE_SET register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be set. When the VINT[a]_ENABLE_CLEAR register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be cleared.

11.2.4.2.2.5 Global Event Counting

When enabled, the INTAGGR will provide a set of counters which will track how many outstanding messages have been observed for each ingress event index from the ingress Counted Global Event Transport Lane (ETL) interface. For each message received where the 'UpDn' flag is set, the corresponding counter will be incremented by value of the 'cnt' field of ingress message. Events where the 'UpDn' flag is cleared are ignored. The counter is made visible to software in the GEVI[a]_COUNT register. When software has read the count, it can acknowledge that count has been seen and processed by writing back an integer value specifying the amount by which the counter should be decremented, and the counter will subtract that value from the current count (which may have updated since it was read). The count will saturate at a value of 0xFFFFFFFF. Writing a count 'ack' value higher than the one read is not supported and will produce non-deterministic results.

When a count transitions from zero to a non-zero value, a Global Up 'UpDn=1' event is sent out an egress ETL interface. When a count transitions from a non-zero value to zero, a down 'UpDn=0' event will be sent. The index of the Global event is mappable on a 'per-counter' basis, using the GEVI[a]_MAP register. The event may be mapped such that it then re-enters INTAGGR's 'Event to Interrupt Bit Steering Block' to generate an interrupt to the host. The event routing is handled by an external event switch fabric. Note that writing a new egress event index via the GEVI[a]_MAP register does not alter the stored event count for the ingress event register index.

Copyright © 2024 Texas Instruments Incorporated

11.2.4.2.2.6 Local Event to Global Event Conversion

When enabled, the INTAGGR will provide a set of Local to Global event conversion registers. Local events may be discrete clock synchronous pulses or clock synchronous rising edges. The counting mode is configurable on a 'per pin' basis. In pulsed mode, the module will track how many outstanding clock cycle long pulses have been observed on each of the provided levi interface pins. For each cycle in which a LEVI input pending bit is asserted the corresponding counter will be incremented by 1. In 'rising edge' mode, the number of rising edge transitions on the pin is counted.

The module will generate egress Global events on its egress ETL, with a different global index configured for each ingress LEVI pin. The LEVI pins numbers (1-N) are converted to arbitrary global event indices via the global event mapping LEVI[a]_MAP registers. The egress Global events can themselves be mapped to re-enter the INTAGGR's Global Event Counting block, so that the counts can then be made visible to software in the GEVI count registers as described in Section 10.2.7.3.1.3. The event routing is handled by an external event switch fabric.

11.2.4.2.2.7 Global Event Multicast

In DMSS0_INTAGGR0, the INTAGGR will provide a set of Global event multicast (GEVI[a]_MCMAP) registers. These registers allow an ingress Global event on its ingress ETL interface to be mapped into two egress Global events on two separate egress ETL interfaces. A set of registers map the ingress Global event index (1-N) into two arbitrary egress event indices.

11.2.5 Packet Streaming Interface Link (PSI-L)

This section describes the Packet Streaming Interface Link (PSI-L) for the device.

11.2.5.1 PSI-L Overview

PSI-L is a packet based protocol used to transfer data between several device modules. Each transaction is routed based on thread ID value instead of physical address. All PSI-L interfaces are point to point direct connections to DMSS0. All switching functions among the PSI-L based interfaces are done inside DMSS0.

The PSI-L also has an event interface referred to as ETL, which is purely used to transfer event information.

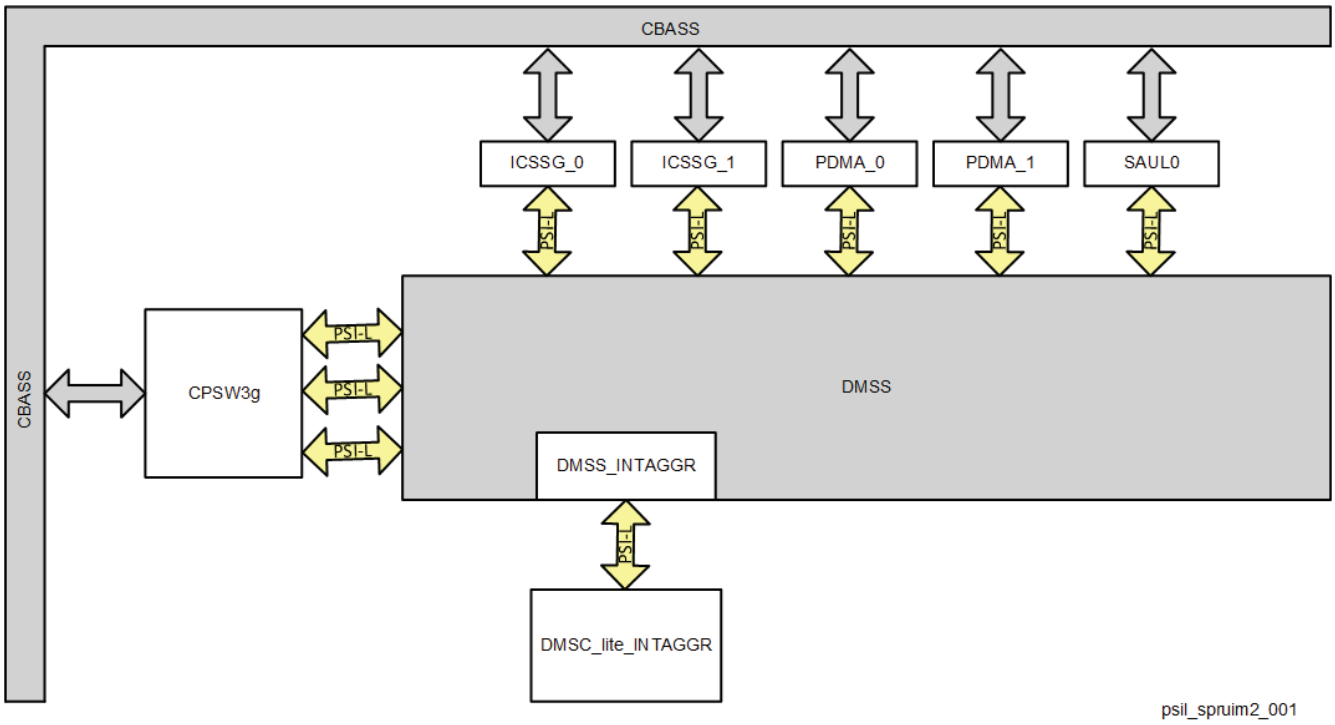

Figure 11-9. PSI-L Overview

Copyright © 2024 Texas Instruments Incorporated

11.2.5.2 PSI-L Functional Description

11.2.5.2.1 PSI-L Introduction

The PSI-L is used to transfer words of packet data and control information between two peer entities via direct connection. There are credits used for flow control to guarantee that blocking does not occur between threads. Multiple packet transfers can be ongoing simultaneously across a PSI-L interface each on a separate logical thread but all sharing a single data path through time division multiplexing. Each packet which is transferred is accompanied by a destination thread ID which indicates the logical destination thread to which the packet is being sent.

There is low level hardware handshake between PSI-L initiator and target used for transferring data. As it is blocking by nature, a higher level protocol is also used in which credits are maintained for each thread connection. Moments of non-readiness are allowed on the interface but there is no possibility that one thread can block another for an indefinite time since a thread must have credit for the destination before it is allowed to use the interface.

Figure *PSI-L Connection* illustrates the point to point PSI-L connection.

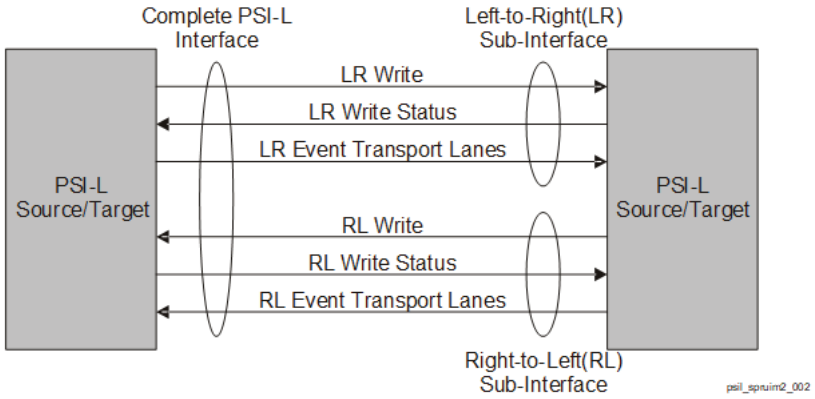

Figure 11-10. PSI-L Connection

PSI-L is intended to be a versatile interface which can carry various types of communications. The following table describes several types of threads which have been defined.

Table 11-75. Types of PSI-L Threads

Type	Description	Example Endpoints
Queue Management (QM) Messaging	Provides transport for queue push, pop, and divert messages to support distributed queue based work passing	Centralized queue manager or message manager and distributed DMA clients
Direct IO	Allows for tunneling CBASS compatible bus transactions through a PSI interconnect	Module which has no CBASS initiator to a remote proxy block
DMA Control Transport	Provides transport for DMA transfer descriptions from a source thread to a destination thread	DMA channel controller to DMA transfer controller
DMA Data Transport	Provides transport for packed data from a source thread to a destination thread	Packet oriented module like networking adapters to or from centralized DMA

Each thread on PSI-L is established between a single thread initiator and a single thread target using a connection oriented transfer mechanism. A thread initiator and a thread target are "paired" to create a logical connection between them referred to as a thread. Pairing is accomplished using a Pair Configuration Message which is valid in all thread types. Pairing can only occur between a thread initiator and a thread target of the same type.

Copyright © 2024 Texas Instruments Incorporated

11.2.5.2.2 PSI-L Operation

The PSI-L allows multiple independent streams of packet data (threads) to share a single interface using data phase granularity time division multiplexing. This time division multiplexing is accomplished by dividing each stream into single data transfers. In this way a stream is comprised of a sequence of strongly ordered data transfers but packet transfers between different streams are allowed to be interleaved. Each data phase is qualified with a type identifier which indicates whether the data is packet info, direct IO write or read info, timestamp, software info, control data, payload data, or status.

11.2.5.2.3 Event Transport

PSI-L provides a mechanism by which events can be transported within one or more optional subinterfaces on a link. These sub-interfaces are referred to as event transport lanes (ETLs) and are independent of any PSI-L packet or message transfers which may be ongoing on the other interfaces within the PSI-L. A maximum of one event can be transferred on each event transport lane in each clock cycle. The event transport protocol is a simple request-ready type of hardware handshake.

11.2.5.2.4 Threads

A thread is a complete flow-controlled stream of communication. The PSI-L thread space is divided into a 32K contiguous region representing all of the source threads (0x0000 - 0x7FFF) and a 32K contiguous region representing all of the destination threads (0x8000 - 0x8FFF).

Source threads are responsible for sending request transactions, accepting response transactions, and sending data transfer transactions. Destination threads are responsible for accepting request transactions, sending response transactions, and accepting data transfer transactions. A given thread generally performs only a single class of transactions (see Table *PSI-L Defined Threads*). Both source and destination threads may act as initiators for transfers on one of the PSI-L write sub-interfaces but in this case source threads are actually initiating data transfers while destination threads are only responding to a previous request issued by a source request. Source threads only transfer to destination threads and destination threads only transfer to source threads. Transfers between same thread types do not occur.

The following types of message transfers always originate from source threads and terminate in destination threads:

- Configuration write message
- Configuration read message
- QM push message
- QM pop message
- QM divert message
- Direct read operation message
- Direct write operation message
- DMA transfer request message
- DMA data message

The following types of message transfers always originate in destination threads and terminate in source threads:

- Configuration write response message
- Configuration read response message
- QM push response message
- QM pop response message
- QM divert response message
- DMA transfer response message

11.2.5.2.5 Arbitration Protocol

On each cycle, an arbiter built into the initiator side of each interface decides on which thread to transfer data in the next clock cycle. Both forward (from source threads) and reverse (from destination threads) direction

Copyright © 2024 Texas Instruments Incorporated

transfers can occur across the same physical interface so the arbiter must ensure that sustained blocking of any thread can occur.

The decision about which thread to allow using the interface is based on the following factors:

1. Whether data is ready at the source to be sent
2. Whether credit exists for the thread such that it is guaranteed there is a place for the data to land in the destination endpoint. For reverse direction transfers (response messages), it is assumed that credit always exists.
3. The relative priority of the traffic that the thread is carrying for the given packet duration
4. Whether the transfer is for a forward or reverse direction thread (requests versus responses).

No thread can be considered for inclusion in arbitration unless both data is available and credit exists in the destination endpoint. For each thread which can be considered in the current arbitration cycle, the arbiter should then pick the thread with the highest priority. Reverse transfers should be considered higher priority than forward transfers.

11.2.5.2.6 Thread Configuration

Each source thread has programmable registers for configuring the pairing with a corresponding destination thread and for enabling data flow. Each destination thread has programmable registers for reporting the buffering capability of the thread and for enabling data flow. These registers are accessed using configuration read and write messages from a configuration host.

Each configuration write message sent from a configuration host is acknowledged with a configuration write response message from the addressed endpoint. Each configuration read message sent from a configuration host is acknowledged with a configuration read response message from the addressed endpoint.

11.2.5.2.6.1 Thread Pairing

Depending on the type of traffic that each source thread carries it may or may not have a fixed pairing with a destination thread.

11.2.5.2.6.1.1 Configuration Transaction Pairing

Configuration write and read transactions are only initiated by a special module called configuration proxy (PSILCFG_PROXY). Each configuration proxy in the system uses a single source thread which can initiate configuration write and read transactions to the configuration registers of every other source and destination thread in the PSI-L system. The PSILCFG_PROXY registers are described in *DMASS_PSILCFG_0 Registers*.

Each source thread routes to a single target thread and this pairing is specified by programming a required pairing register set for each thread. A source has no ability to change what target thread it talks to. If a source must be able to talk to different targets (or target threads), then it can either have multiple threads or a streaming switch that can be programmed to route the transfers appropriately based on specific packet fields.

11.2.5.2.6.2 Configuration Registers Region

The configuration registers region contains static configuration information including the settings for linking a thread source to a thread destination. These registers are described in *PSIL Configuration Registers* . The thread ID mapping is shown in the PSI-L System Thread Map in *Module Integration*.

11.3 Peripheral DMA (PDMA)

This chapter describes the PDMA architecture in the device.

11.3.1 PDMA Controller

11.3.1.1 PDMA Overview

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals, which perform data transfers using memory mapped registers (MMRs) accessed via a standard non-coherent bus fabric. The PDMA module is located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured transfer request (TR) operations.

The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer DMSS destination channel which then performs the movement of the data into memory. Likewise, a remote DMSS source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The PDMA architecture is intentionally heterogeneous (DMSS + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

There are two PDMA modules in the device. Table 11-76 shows PDMA allocation across device domains.

Table 11-76. PDMA Allocation across Device Domains

PDMA Instance	Serviced Peripherals	Domain	
		MCU	MAIN
PDMA0 - SPI	SPI0, SPI1, SPI2, MCAN0	–	✓
PDMA1 - UART	UART0,UAR1,UART2,UART3,UART4,UART5,UART6	–	✓
PDMA2 - McASP	McASP0, McASP1, McASP2	-	✓

The PDMA is linked to the DMSS through a direct PSI-L connection. For more details, refer to *Packet Streaming Interface Link (PSI-L)*.

11.3.1.1.1 PDMA Features

11.3.1.1.1.1 PDMA0 - SPI Features

The PDMA0 - SPI module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit(s)
  - Each unit supports write bursts up to 64 bytes (on selected channel types)
  - Write Unit 0
    - Provides a 32-bit wide VBUSP write-only initiator interface for peripheral accesses
- Provides 1 memory read access unit(s)
  - Supports 1 outstanding read per interface (VBUSP)
  - Supports read burst up to 64 bytes (on selected channel types)
  - Read Unit 0
    - Provides a 32-bit wide VBUSP read-only initiator interface for peripheral accesses
- Supports up to 15 simultaneous destination (Tx) channels
- Supports negative credit monitoring on Tx channels

Copyright © 2024 Texas Instruments Incorporated

- Supports up to 15 simultaneous source (Rx) channels
- Supports Static Transfer Requests Only
- Supports X-Y, MCAN, and AASRC transter modes (as per configuration)
- Provides per-channel buffering:
  - Provides 8 128-bit word deep data FIFO for each destination channel
  - Provides 8 128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to and from DMSS endpoints and remote peripherals

11.3.1.1.1.2 PDMA1 - UART Features

The PDMA1 - UART module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit(s)
  - Each unit supports write bursts up to 64 bytes (on selected channel types)
  - Write Unit 0
    - Provides a 32-bit wide VBUSP write-only initiator interface for peripheral accesses
- Provides 1 memory read access unit(s)
  - Supports 1 outstanding read per interface (VBUSP)
  - Supports read burst up to 64 bytes (on selected channel types)
  - Read Unit 0
    - Provides a 32-bit wide VBUSP read-only initiator interface for peripheral accesses
- Supports up to 7 simultaneous destination (Tx) channels
- Supports negative credit monitoring on Tx channels
- Supports up to 7 simultaneous source (Rx) channels
- Supports Static Transfer Requests Only
- Supports X-Y, MCAN, and AASRC transter modes (as per configuration)
- Provides per-channel buffering:
  - Provides 8 128-bit word deep data FIFO for each destination channel
  - Provides 8 128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to and from DMSS endpoints and remote peripherals

11.3.1.1.1.3 PDMA2 - McASP Features

The PDMA2 - McASP module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit(s)
  - Each unit supports write bursts up to 64 bytes (X-Y FIFO transfer mode only)
  - Write Unit 0
    - Provides a 32-bit wide VBUSP write-only initiator interface for peripheral accesses
- Provides 1 memory read access unit(s)
  - Supports 1 outstanding read per interface (VBUSP)
  - Supports read burst up to 64 bytes (X-Y FIFO transfer mode only)
  - Read Unit 0
    - Provides a 32-bit wide VBUSP read-only initiator interface for peripheral accesses
- Supports up to 3 simultaneous destination (Tx) channels
- Supports up to 3 simultaneous source (Rx) channels
- Supports Static Transfer Requests Only
- Supports X-Y, MCAN, and AASRC transter modes (as per configuration)
- Provides per-channel buffering:
  - Provides 8 128-bit word deep data FIFO for each destination channel
  - Provides 8 128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to and from DMSS endpoints and remote peripherals

Copyright © 2024 Texas Instruments Incorporated

Note

Some features may not be available. See *Module Integration* for more information.

11.3.1.2 Functional Description - SPI

11.3.1.2.1 Compliance to Standards

The PDMA complies fully to all standards listed in the previous section.

11.3.1.2.2 Functional Operation

The Peripheral DMA is a simple, low cost implementation of the CPPI 5.0 Unified Transfer Controller. The PDMA module is required to be located close to one or more peripherals (both peripherals and PDMA direct connected to the SCR) which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only the static Transfer Request subset of UTC features which are useful for peripheral type transactions. Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs time division multiplexing between channels in order to share the underlying DMA hardware. A scheduler is provided to control the ordering and rate at which this multiplexing occurs. A block diagram of the PDMA Controller is shown below.

11.3.1.2.2.1 Submodule Descriptions

11.3.1.2.2.1.1 Scheduler

The Scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low level read or write operation.

11.3.1.2.2.1.2 Tx Per Channel Buffers

The Tx Per Channel Buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx Per Channel Buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

11.3.1.2.2.1.3 Tx DMA Unit
